

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

YOU BUY MORE THAN SERVICE IN A G. V. ELECTRIC

Successful motor truck operation today consists in having a properly applied installation and an operating policy that avoids the mistakes that have proven so disastrous to others.

Your profits from this mode of transportation are therefore determined largely by the quality of your purchase.

Practically every purchaser of a G. V. Electric is a man who had to be thoroughly convinced of its time and money saving possibilities before he decided to buy. Once installed it devolves upon the G. V. Electric to "make good" the promises made for it, and a distribution now numbering nearly 4000 G. V. Electrics in daily service should satisfy the most biased that it does serve to the profit of the user.

And always remember that every problem we overcome adds to the worth of the experience you buy into as a G. V. purchaser.

"Each Replaces Five to Six Teams"

The R & L Company,
Eastern Agents for the Garford,
New York City.

Dear Sirs:—

In accepting your proposition to furnish us with six more five-ton Garford dump trucks, for which you will find signed contract herewith, we desire to express our complete satisfaction with the two Garford trucks we have had in use for the last six months. *Each one has replaced from five to six teams.* Their operation has been constant and dependable, so that we are now fully warranted in putting in a complete motor truck equipment.

The service and inspection have been thoroughly satisfactory and we can only speak in the highest terms of the treatment received from your company.

We propose to sell off 40 to 50 horses as soon as the motors are delivered, therefore please rush this order through as quickly as possible.

WATSON CONTRACTING COMPANY,
Contractors and Stevedores,
2612-15 Aqueduct Ave., New York

Garfords are effecting like economies in many lines of business. Send for catalogue.

Please address Dept. 25.

PAWTUCKET, R. I., JANUARY, 1914

No. 1

FREIGHTING OYSTERS AT EXPRESS RATES.

Two Peerless Trucks Make Round Trip of 130 Miles Daily Between Warren, R. I., and Boston, Giving Better Service Than the Railroads and Materially Improving the Business of the Wholesale Shellfish Dealers.

MAKING a daily mileage of 130 in the haulage of oysters between Warren, R. I., and Boston for five days each week, and competing directly with the Adams Express Company, two Peerless trucks owned by Frank Cotrone & Co., Providence, R. I., have been driven more than 11,000 miles each since Sept. 1, 1913, and the freights have been delivered before the beginning of business to all the consignees, with the exception of three days when the machines were slightly delayed en route.

This is probably the longest daily haul made in America, and one of the best demonstrations ever made of the use of machines in direct competition with

tion and resources of one of the largest public service corporations of the country.

The real possibilities with the use of trucks have been very well established, but it should be understood that with greater experience and knowledge of conditions economies can be attained that would minimize expense and insure a larger measure of profit. Obviously a man who had been doing general contract haulage work could not turn to transportation of this character and at once realize the greatest productiveness, for this must result from study of every aspect and careful observation of every phase of operating and the general requirements of the customers.

The Motor Trucks Owned by Frank Cotrone & Co., at the Garage in Globe Street, Providence, R. I., in Readiness for the Collecting Trip to Warren.

the most efficient public service that is afforded the people. There are those who assume that motor trucks can be utilized to excellent advantage for haulage that is too severe for animal vehicles, and that they are practical for the conveyance of freight for distances from 20 to 40 miles where the demands are for quicker service than can be afforded by the usual facilities of the average steam railroad, but comparatively few believe that these machines can be operated to serve the people with greater regularity and more satisfactory results than is possible with the organiza-

Warren, R. I., is known to comparatively few, no doubt, but there is not a person with epicurean tastes who does not know that the finest oysters of America are those grown in Warren river, at its confluence with Narragansett bay, where the conditions are such as to cause them to grow to large size without becoming tough and where a flavor is imparted that is unequalled in oysters grown elsewhere. "Warren river fancies" are specially grown and are in great demand, being sold to the best hotels, cafes, clubs and the like. The supply is limited, and for this reason those who

Four-Ton Peerless Truck That Has Been Driven Nearly 11,000 Miles in Four Months, Carrying Oysters Between Warren, R. I., and Boston, a Round Trip of 130 Miles.

control oyster growing in the comparatively small Warren river beds cannot only dispose of all that can be dredged, but can command high prices. Oyster growing is an industry of considerable proportions in Warren, and along the river are the wharves and houses of companies that carry on oyster culture with system and scientific methods. The oyster growers have developed markets comparatively near, and aside from the towns and cities within a radius of 25 miles the bulk of the yield is sold in Boston.

Warren River Oysters.

Oysters are sold in the shell, as taken from the water, and "opened". The unopened oyster can be kept several days with care, and some of the Warren river crop is shipped in the shell and opened as used, but a very considerable part of the yield is opened and the flesh and liquor sent to market ready for use as food. Only when the oyster is to be served in the shell or "fresh-opened" is it shipped unopened. While the shell oyster is the better preserved and retains its flavor and delicacy, there is little loss in quality of the opened oyster if used within a reasonable length of time. Shell oysters must be shipped in barrels and iced as a precaution against temperatures higher than that of water. A bushel of shell oysters will yield a gallon of flesh and liquor, and adding the cost of transporting and of the labor of opening to the price at the shore, one will see that from the viewpoint of the wholesale or retail dealer the opened oyster is to be preferred to the shell oyster.

The companies engaged in the oyster industry at Warren usually contract to supply stated quantities to customers. The oysters are opened fresh each day and are shipped in cans packed in tubs of ice, much the same as ice cream is transported, the tubs being closed with clamped covers to retain the cold air and minimize the meltage of ice. When sent out in wholesale quantities the cans are 10 gallons capacity and the fully iced tubs and filled cans weigh about 115 pounds each. When shipped in this manner oysters can be sent considerable distances. Being perishable, however, expedition in handling and transit is necessary,

and for years shipments were sent by express.

Shipping by Express.

The oyster season is from Sept. 1 to May 1, and during these eight months the consumption is very large, but the remainder of the year a comparatively small part of the ordinary yield is sold. Until the present season the oyster growers filled their orders and the tubs were taken from the "houses" by drivers of the Adams Express Company and shipped from Warren to the individual customers. Warren is served by the

electrified Providence, Warren and Bristol branch of the New Haven road, and from this point the shipments were distributed. The greater part of the tubs dispatched are taken by Boston customers, usually wholesalers, and these in turn distribute the oysters from their Boston stores. These tubs were sent to Providence and there transferred to express cars on the steam railroad, taken to Boston and there delivered to the customers.

This manner of shipping necessitated seven handlings, the collection and shipment at Warren, the unloading and reloading at Providence, and the unloading, loading and delivery at Boston. To insure forwarding by express the tubs had to be in readiness by 4 in the afternoon, and they were sent out with the regular shipments. For years the tubs were made ready by the growers and the express company notified, this ending the responsibility of the shippers. Each consignment was separate and if the shipments were ready any delay was up to the express company. The tubs were supposed to be delivered before or by 7 each morning, but anywhere from 7 until 12 was the actual time they were received, with 9 as perhaps a fair average. The Boston consignees demanded that the deliveries be made at 7 because the oysters were stock in trade that was necessary for the transaction of business, and delay in the morning meant retardation of local shipments and deliveries, dissatisfaction of customers and more or less loss to them.

The Adams Express Company received remonstrances, individual or concerted, from every man receiving Warren river oysters, until the dealers were absolutely discouraged. Unless the stock could be received on time business was decidedly uncertain, and the trade demands could not be denied. The express company was master of the situation and delivered the tubs on a go-as-you-please basis.

This was the condition last April just before the close of the season. The Warren growers were hopeless. They believed that their market was more or less affected by the uncertain service and prices necessarily influenced, but earlier shipment by them would

not bring about a change in delivery. Being informed of the facts Mr. Cotrone visited the Warren growers and got a list of their customers in Boston. Then he interviewed the Bostonians. He told these men that he had two trucks with capacity for carrying nine tons of freight, that he would bring the tubs of oysters over the road to them each night and would undertake to make delivery at any hour desired in the morning. There was some doubt expressed as to the dependability of the trucks when the long hauls were considered, but Mr. Cotrone maintained that if he couldn't do the work the contract need not continue, and the best insurance he could give until he had proven what was possible and practical, was his word, based on his experience with the machines. The Boston men were asked to pay the same price they were paying the express company, both for hauling the tubs to Boston and returning them when empty, the benefit they were to receive being delivery at 7 in the morning and being able to do business with their customers with certainty. So general was the dissatisfaction among them that all accepted the proposition, and arrangements were made for truck transportation when the season opened.

Mr. Cotrone lives and has a garage in Globe street, Providence, and he makes his headquarters there, this location being not far from the direct route from Warren to Boston. As the oyster fishing is somewhat dependent upon weather conditions, and the shipments must be fresh, the orders are not made up until late in the afternoon, and sometimes in the early evening. This necessitates waiting until the end of the day before the collection could be made, and so the trucks are sent to Warren from 3 to 4. The tubs are packed and placed on platforms at the oyster houses and are generally ready between 4:30 and 6:30. The five-ton truck has a short body and a standing top with removable side slats, these being covered with curtains. Into this 100 tubs can be packed in three tiers, but the four-ton truck has a stake platform body that will take two tiers of 40 tubs each, so that when fully loaded the machines have a normal capacity of 180 tubs, each containing 10 gallons of oysters.

How Shipments Are Made.

Because of the desire to sell all stock so there shall be none on hand Sunday, no opening is done Saturdays at the oyster houses other than to supply local demand, and the tub shipments are made the first five days of the week, there being practically no supply in the Boston market for Monday. The trucks are not operated in this work from Saturday noon until Monday afternoon. The necessity of systematizing the loading so that the tubs could

be delivered to the consignees with minimum handling was apparent, and after the route in Boston had been decided the loads were systematically collected. A few trips were made before the better route for delivery could be determined, but a majority of the Boston dealers are located in Atlantic avenue and most of the others in sections of the city that can be conveniently reached.

After loading the trucks are driven to Providence and to the garage, where they are kept until midnight, when the start is made for Boston. Five hours is slow time for the run, because when the truck is started it is kept moving, and with no obstructions and a comparatively clear road a uniform speed can be maintained. In constant driving over the road the drivers become very familiar with conditions that usually obtain. With normal weather the trucks are driven through in very close to a given time, arrival being governed somewhat by the time of departure.

When the first few trips were made the trucks were often at the stores before clerks were there to receive the shipments, for all tubs must be signed for, but after that the stores were in readiness and the machines were not compelled to wait or return. As the deliveries are made the empty tubs are collected and these will vary from day to day, as will the loads. The return is made over the same route and usually by 1, and sometimes by 12, the trucks are back at the garage in Providence.

Comparison with Express Service.

The loss of the business was not pleasing to the executives of the Adams Express Company, and after solicitation and other means had failed to induce the oyster dealers to abandon the truck service the company offered to get the tubs through at the time that it had formerly been expected to, and to return the tubs to Warren free of transportation charges. The dealers, however, realized the benefit of the overland freight line and the majority of them continued their patronage, although they are paying for the return of the tubs. With the trucks operated daily the express deliveries are now made very promptly at 7, in strik-

Five-Ton Peerless Truck That Makes Trips of 130 Miles Five Days a Week Between Warren, R. I., and Boston, and Has Been Driven More Than 21,000 Miles in a Year.

ing contrast with the delays of previous years. The dealers realize that with the motor service for their exclusive benefit and controlled by them they can have their own desires satisfied, and without it they would be no better off than they were before. For this reason they have not listened to the proposition of the express company.

The business is good for eight months of the year, and after that time it is doubtful whether there will be sufficient freight to justify the operation of the trucks, but this is a matter for future consideration. The trucks earn the regular express rates for one way, and the express charges for the return of the empty tubs, but the latter is a comparatively small amount when contrasted with the former. For this reason, from the viewpoint of the owner, the trucks are not as profitable as they could be were there full freights both ways. The long runs necessitate care to have the machines in good condition at all times, for the loss of a trip would be a serious matter. From three to four hours each afternoon and about the same time each night is available for repair or adjustment, and from Saturday afternoon until Monday afternoon for work that is of considerable consequence. Mr. Cotrone drives one of the machines himself, and another driver and three helpers make up his working force. The drivers go through with the machines each night, but the helpers alternate on the trips, for they assist in collecting the load.

The Truck Equipment.

The entire repair and care of the machines is directed by Mr. Cotrone, who is an expert machinist, and he says that he has had no occasion to take them to a repairer, for in the event of need he can avail himself of the use of the machine tools in the shop of a friend, and he has the experience that fits him for any work that may be necessary. He was working in a machine shop in 1912 and late in the summer bought an Alco truck and made a contract with a coal company to haul fuel. He sold this machine after using it about four months and purchased the five-ton Peerless truck. This he used in contract coal and in contract construction work haulage, and at the opening of the summer resorts on the east shore of Narragansett bay last season he bought the four-ton Peerless truck and equipped it with a passenger body. He used this for public service between Providence and Crescent Park until the contract for freighting the oysters was made.

Both trucks are fitted with six-inch forward tires and six-inch dual tires on the rear wheels, and with these the results are reasonably satisfactory, but the long daily runs cause the tire cost to accumulate rapidly. The tire expense of the smaller machine is, however, because of its equipment with larger tires than is generally used for its capacity, proportionately less than for the larger truck. Aside from the cost of fuel, as the five-ton truck is geared lower and will consume about five gallons more gasoline in a run of 130 miles than the four-ton, there is but little difference in the

operating expense of the two vehicles. The smaller truck is limited to 14.8 miles an hour at 975 revolutions a minute, and yet it is seldom driven to that speed. The five-ton machine is geared to 10.8 miles an hour with the same engine speed.

The machines are carefully driven and being worked under the supervision of the owner they are not abused. For about eight months the five-ton truck was driven an average of 50 miles a day, and with the Boston-Warren route work the mileage for the year is approximately 21,000. The four-ton truck was driven for about four months in passenger service an average of at least 100 miles daily, and this and the Boston-Warren route trips will give an aggregate of about 25,000 miles. The work done by the two machines is double what would be regarded as good mileage in average work for the period of use, and reliability has not lessened with service. The work has been well systematized, and the service may be said to be reduced to a very practical degree of productiveness. It will be continued until the end of the oyster season, and there is reason to believe that truck transportation will be preferred from now on by the oyster growers. The development of other freighting over the road has not been considered, but it will receive attention as soon as time can be given to it.

A meeting of the creditors of the Lansden Company, Newark, N. J., which concern is now in the hands of Henry L. Davison, trustee in bankruptcy, will be held in Newark, Jan. 21, at which time sealed bids for the property of the company, either as a whole or divided, will be considered. The valuation of the factory property, its equipment, material, etc., including an allowance of \$10,000 for drawings, blue prints and patterns, is \$125,724.70.

The completion of two six-story buildings, 170 by 198 feet and 70 by 128 feet respectively, has increased the plant of the International Harvester Company at Akron, O., devoted to the production of power wagons, about 100 per cent., and when worked to its normal capacity the factory will turn out 30 machines daily.

The use of four trailers with a three-ton KisselKar truck, making a train that will carry the average load of a railroad freight car, has been found by the Kansas City Transfer Company to be a very economical manner of haulage.

The capital stock of the Hartford Rubber Works Company has been increased from \$1,000,000 to \$2,000,000, which is offered in preferred cumulative six per cent. stock at par.

A. W. Frantz has been named general manager of the Cass Motor Truck Company, Port Huron, Mich., which has been reorganized and has resumed business.

COMPETING WITH RAILROAD HAULAGE.

First Overland Express in Rhode Island with "Tailboard" Delivery, Rounding Out Third Year of Service---Plans for Expansion and Increased Equipment.

THOSE who question the endurance of motor trucks and wagons will not take issue with the statement that a period of about three years of constant service is a sufficient test on which to base judgment, and for this reason the experience of the Providence and Woonsocket Motor Trucking Company, which operates a highway transportation line between Providence and Woonsocket, R. I., justifies an unusual attention from those interested in road haulage. Since March, 1911, the company has used one truck, and for more than two years has operated a second, and not only are the machines giving as good service now as when first received, but they have every promise of being useful for several years more.

The company was the first to operate a motor truck for regular overland express work in Rhode Island, and its No. 1 machine was the third sold by the maker in the state. The company was formed by James Potter and a partner for the purpose of competing with railroad and trolley freight and express companies, as well as several concerns using horses. Strangely enough, Mr. Potter had been engaged in railroad work for 25 years, and it was his knowledge of the limitations of the steam and trolley road facilities that prompted him to enter competition for the business.

From centre to centre Providence and Woonsocket are 16 miles apart, the latter being tucked away against the boundary line between Massachusetts and Rhode Island, and both the tracks of the New Haven road and the highway follow the Blackstone river north, the road climbing gradually until Cumberland Hill is reached, when it descends into a basin surrounded by hills in which the northern city is located. While the highway is smooth and well surfaced the grade ascends constantly going north, and from Woonsocket to Cumberland Hill going south there is a hard uphill haul for about three miles. These conditions are stated to make clear why overland haulage with horses means long and hard trips and comparatively light freights, especially in bad weather.

No Competition by Railroads.

Before the days of the railroads the Blackstone canal was built for freightage between the mills and villages that had been established at short intervals

in the valley, and after the operation of freight trains this was abandoned and the railway practically monopolized the traffic until the completion of the trolley lines. The acquisition of the electric roads by the New Haven system practically eliminated these from serious competition.

Woonsocket is a thriving and prosperous manufacturing city, most of its industries being textile mills, and the railroad has for years profited by the rates charged for the comparatively short haul, the freight service being exasperatingly slow and undependable. Woonsocket business men say without hesitancy that both commercial growth and industrial development have suffered because the railroad has not provided the facilities that would stimulate local prosperity, and a great deal of purchasing is done in Providence because the stores and shops cannot supply the immediate de-

Packard Three-Ton Truck, First Machine to Be Used in Overland Express Work in Rhode Island, Driven 45,000 Miles Since March, 1911.

mands of customers, largely from slow freights and infrequent express service. In other words, the railroad was absolutely indifferent to the people and from every point of view its service was a handicap instead of being promotive.

Mr. Potter had no experience with highway haulage of freight, but he had confidence in motor trucks and believed that the business men of Woonsocket would patronize his enterprise. He talked with a number who assured him that he could depend upon their support, and he found numerous Providence firms that were equally well disposed. While he was somewhat uncertain as to what service would meet the most success, he realized that a machine to meet his requirements and insure a reasonable return on the investment, should have considerable capacity. His deci-

sion was to purchase a three-ton Packard truck, and this was equipped with a standing roof, with removable side slats, so that freight could be loaded or unloaded at the sides as well as the rear.

Service Planned to Serve Many.

Mr. Potter's home is in Providence and he arranged a schedule so he could leave his last place of call in that city by 9 o'clock, going north through the Fairlawn section of Pawtucket, Saylesville, West Lonsdale, Berkeley, Ashton and Cumberland Hill, and returning to go through Cumberland Hill, Ashton, Berkeley, East Lonsdale, Valley Falls, Central Falls and Pawtucket, stopping en route to make deliveries or collect freight. He estimated his running time as two hours, and as he promised a delivery from the truck to the store or mill, this meant that considerable time would be required for making the calls for delivery and collection. By leaving Woonsocket at 2:30 or thereabouts he expected to make all calls returning and reach Providence by 5 or 5:30, this making possible deliveries before the close of business.

This was a tentative schedule, and it provided for one round trip daily, but the condition that appealed to the business men was the prospect of getting an early morning order shipped from Providence and delivered before noon, or of sending goods to Providence before the close of business there, or of making connection with the New York steamer lines. The Providence office was established with the Union Express Company, which is the headquarters of 13 overland express companies, and starting mornings at 6:30 or 7 o'clock, collections were made from different wholesale stores, leaving for the Woonsocket run at 8:30 or thereabouts. The two partners did all the work, both driving the truck, and Mr. Potter's railroad experience was a considerable asset, for he realized the value of a schedule time of arriving and leaving, this meaning much to business men who desire to convenience and accommodate their customers.

The rates established were between the railroad freight and the large express company prices, and considering the service these may be regarded as very moderate, for the quick delivery at either end or along the route could not be equalled from the average express route, while between terminals no distribution is made systematically by any concern. Regarded from the saving of time and the independence of the railroads the company is at least entitled to express rates, but as the start was made without a patron, and the investment was justified merely by the assurances given, the prices were necessarily made as low as possible.

Second Truck Necessary.

Mr. Potter's brother-in-law was his first partner, and after about nine months this man retired and was succeeded by another man, and later this man withdrew and Patrick Conway purchased the interest. Before the end of 1911 the second truck, also a three-ton Packard, was bought, for the business had at that time been developed to such an extent that it could not be

carried with the original machine. Since that time both have been operated, practically on the schedule stated, and as a rule the freights each way are capacity loads. With the two trucks the work is divided, each calling at regular customers and making collections and deliveries independent of the other, unless there is occasion for one taking freight that the other cannot.

Both cover the same route going north, but one machine returns over this and the other goes through East Lonsdale, Valley Falls, Central Falls and Pawtucket, this insuring full service to each customer south of East Lonsdale. Trips are made each business day of the year, and with nearly three years' experience storms or road conditions have practically no effect, the machines going through with little or no loss of time. The only time that trips have been lost were when the trucks were withdrawn for overhauling or large repair. Good time can be made on the highway under nearly all weather conditions, the running time averaging about an hour and 30 minutes. The machines are governed to 18 miles an hour, and are seldom driven to maximum speed.

The conditions with reference to delivery from the trucks to the stores, shops and factories are such that very little time is lost in unloading. With this particular service the only handicap is the fact that the customers are often widely scattered and delivery and collection at Woonsocket, for instance, will necessitate from five to 10 miles driving, while in Providence the average is very nearly the same. Generally the trucks may be driven directly to the places of delivery, and with the drivers and helpers handling them the freights are quickly discharged, there seldom being cause for delay. Uncertain addresses sometimes require inquiry, but information is generally obtainable from the shipper, and store and shop shipments rarely cause a loss of time.

Largest Shippers Waste Much Time.

Surprising as it may appear, however, those who are the largest shippers, and as a rule those who profit to the greatest degree by the use of the service, are responsible for the greatest delays. While they condemn the railroads and the express companies for failure to expedite shipments, and turn to overland freightage because of the demands of customers for quick deliveries, very frequently they cause the trucks to wait because packages are not ready when calls are made, and appear utterly oblivious to the fact that waiting costs the trucking company money. The loss in single instances is of consequence, and the aggregate for a day is considerable. This is a fault that can only be remedied by a definite understanding, yet the partners do not always feel that they are justified in taking issue with their patrons and for this reason have been tolerant of a loss that is of decided importance. In other words, they have not believed themselves sufficiently independent to take a stand that would compel the shippers to have the freight ready at a stated time, and the business has not as yet justified

more than the one collection daily at either end.

Were the shippers aware of their own responsibilities, or required to pay for waiting time, there is no question they would make such changes as would minimize the loss, and no doubt two hours a day could be saved. If this were devoted to profitable work the earning powers of the trucks would be materially increased. Driving their own machines and having the greatest interest in their business, the partners endeavor to make every minute productive, and there is reason to believe that were less interested drivers employed the idle time might be considerably increased.

Owners Care for Machines.

The trucks are kept in a barn at Mr. Potter's home that serves as a garage, and here the owners give the machines whatever care and attention is necessary. The ordinary adjustments and replenishments are made each night before the day's work is concluded, and a greater part of each Sunday is given over to thorough examinations and such repairs as require considerable time. If machine work is necessary this must be arranged for at a shop, but everything that can be done with hand tools is accomplished by the owners, the helpers giving such assistance as is desired. The trucks are well kept and are in excellent operating condition. No. 1 machine has been driven close to 45,000 miles, and No. 2 truck approximately 35,000 miles, and practically all of these distances loads have been carried. Efficiency has not been diminished with service and Mr. Potter maintains the trucks ought to be good for at least double the present mileage.

The business has been developed and the possibilities for expansion are believed to be such, that plans have been made to add a third truck the coming spring, and if this project is realized one machine will be kept at Woonsocket and will make its trips in reverse of the route as now operated. With this plan Woonsocket will have an early morning collection and a late afternoon delivery, and Providence will have a late morning delivery and early afternoon collection, provided that the present trucks are operated as they now are. This is, of course, tentative, and may be materially changed. It is proposed to have stations for the receipt and delivery of freight, and to arrange a system of transfer that ought to be productive of considerable patronage.

That hard work and long hours, careful service and close attention to the convenience and accommodation of customers, are necessary in developing a business of this character must be understood, and there is no rose-strewn path to affluence, even with motor trucks. But this concern is

recognized as affording a dependable service and has received this recognition in competition that has been fought out on a quality of service basis.

ANNUAL "EXIDE" DINNER.

The annual "Exide" dinner, which has been for the past six years one of the social features during the Chicago automobile show, being tendered by the Electric Storage Battery Company of Philadelphia, Penn., to electric vehicle manufacturers, their agents and distributors of the company, as planned for this season will take place the evening of Jan. 28 at the Mid Day Club in Chicago. The invitations will be sent out in a very few days. The event has always been notable for an excellent menu, some capital speaking and an entertainment of unusual interest, and it is the expectation of those in charge of the dinner that it will be even a greater success than those of previous years.

PALMER-MOORE EXHIBIT.

During the progress of the national pleasure car show at New York City January 3-10, the Palmer-Moore Company, Syracuse, N. Y., exhibited at Lexington avenue and 48th street three machines, these including an air-cooled chassis with planetary gearset, an air-cooled chassis with open express body and detachable top, and a water-cooled chassis with sliding type gearset and open express body. On the street the company demonstrated an air-cooled chassis with a four-post express body, and a water-cooled chassis with sliding type gearset and a four-post express body. The display attracted much attention.

A hydraulic device that is substituted for the conventional gearset in power transmission is being experimented with by the Waterbury, Conn., Tool Company in a five-ton White truck in the service of that concern. If found practical it will be produced commercially by the company in the near future.

No. 2 Packard Truck of the Providence and Woonsocket Motor Trucking Company, During the Delivery of a Motor at a Well Known Woonsocket Mill.

FREIGHTING IN CITY DELIVERY ZONE.

Experience with Motor Vehicles Replacing Animal Wagons in Suburban Express Service Shows, with Possibilities Not Yet Developed, a Satisfactory Economy.

FROM a financial viewpoint the possibilities of a general expressing business with highway vehicles within the daily delivery zone of numerous large stores, and where there are unusually good freight and express facilities by electric railroads, may not appear alluring, because of the character of competition and the necessarily limited patronage. There is no question, however, that the people demand service that is not always provided for by large corporations, and this statement can be applied to the business of Hathaway's Express, which is operated between Providence and Warren, R. I., serving the people of the towns of East Providence, Barrington, West Barrington and Warren.

These towns are located on the east side of Narragansett bay, the greater part of the people living comparatively close to the shore. There are numerous summer colonies, some of which are densely populated from May to October, and during that period of the year the population is constantly in a state of transition and may be said to be double what it is during the other months. Besides the shore settlements resorts attract very large numbers day and evening during June, July and August. The trade of these towns is regarded at all seasons of such importance that the department stores, large groceries, markets and other firms dealing in general household supplies, as well as the wholesale houses, make regular deliveries each day throughout the year, and some of the local stores are of considerable proportions.

The electrified Providence, Warren & Bristol division of the New Haven road, which extends to Fall River from Warren, as well as a trolley line from Providence to Bristol, afford unusually good freight and express facilities, and as a whole the section may

be said to be unusually well served so far as locality transportation is concerned. But it is evident that the transitory nature of the summer population demands more than the usual service, and the residents have been educated to exacting the warm weather conveniences throughout the year. The main highways through the towns are the equal of any in the state, and for reasonable distances capacity loads can be drawn by animals. From East Providence centre to Warren the villages are comparatively close, and detours are seldom necessary. The statement relative to the conditions is necessary that one may understand the unusually good facilities for freight and express handling and the exceptional delivery service of the large stores at the one hand, which would appear to minimize the volume of incidental haulage, and the reasons for the generally increased requirements of those who might be classified as temporary residents.

Business Well Established.

Hathaway's Express was established a number of years ago and for at least a decade has given a daily service between Warren and Providence. In that period it has become well known, and has developed a patronage that has continued throughout the year with the residents and from season to season with the summer colonists. It is not a large business, but it has been profitable for years and has been developed according to the demands of the people. Undoubtedly the competition of the electric roads and the express companies has limited its growth, and yet it has been the means of the public getting its transportation at moderate expense. But the large volume of business done by the Providence stores and shops that might have been handled with sufficiently low rates is carried by the transportation departments of these

concerns. In fact the regular delivery equipment used by Providence firms in these towns alone includes a number of motor wagons and trucks and animal vehicles.

The founder of the business sold it after he had developed it to practically the proportions it now has, and last March the present owner bought it. The equipment consisted of 10 horses and a half dozen wagons, but only one horse was bought, a Packard two-ton truck being purchased to take the place of the animals. This was an experiment in the sense that

Two-Ton Packard Truck Operated Between Providence and Warren, R. I., Making One Round Trip Daily.

the work was not what might be termed a long haul, and while the work was hard for horses, there was no question that they could be driven on the route for considerable periods with reasonable care.

One Delivery Each Day.

The Packard truck was placed in service and the work was planned to give one collection and delivery a day at either end, this following the custom that had been followed for years, and which appeared to give the greatest degree of satisfaction. At all of the stations along the route of the electric railroad save Warren, no delivery is made of express or freight, and this means that shipments are taken with the understanding that notification is to be given the consignees, this necessitating more or less delay as compared with the average service, while notices sent by mail were comparatively slow.

The truck has been used in a manner that has not realized its full productiveness, and yet it has replaced four two-horse teams. The demands of the business are unquestionably for a larger machine, when the loads are considered. The truck could easily make three round trips instead of one, and this would materially improve the service, but this has not been considered as yet. In one sense the past season was largely experimental and disassociation from horse methods has not been easy for the owner of the service or for the customers he serves.

Warren covers considerable area, and to reach the summer settlements that are served will require from five to eight miles driving daily, this being given over to combined collections and delivery, and this work is done with a horse and wagon instead of using the truck. Orders are received at the Warren terminal and from that point distribution is made. The morning collection is loaded on the truck and the driver of both the machine and the wagon start for Providence, making calls and collections until Riverside is reached, where the horse driver returns to Warren by train and the truck continues on to Providence, the driver collecting en route.

Converted Touring Car Used.

During the summer, when business is heaviest, the truck will reach Providence about 1 o'clock, but at mid-winter the time of arrival is perhaps an hour earlier. The intention was when the truck was purchased, to do all of the work with this, but when the service was greatest in demand calls at the northern end of East Providence could not be given the attention desired because of lack of time. Collections and deliveries had been made in Providence with a single

Converted Pierce-Arrow Machine Used for Collections and Delivery by Hathaway's Express Company.

horse and wagon, and as it was necessary at times to send this vehicle to East Providence, a motor equipment was decided on. A Pierce-Arrow touring car was purchased and converted to an express wagon by strengthening the chassis and installing an open body arranged with a hoop cover support at the rear.

The change of vehicles was decidedly beneficial, because it was possible to do all the work in Providence with the Pierce-Arrow wagon, as well as making deliveries and collections in East Providence, and when necessary it could be sent along with the truck on the Warren route. The usual time of departure from Providence is 4 in the afternoon at this season, and deliveries are made all the way, the arrival at Warren being from 7 to 8 o'clock, and the load remaining is distributed by the truck and the wagon, the larger packages being usually delivered by the machine.

The truck is driven by the owner's son, and the owner and a driver share the driving of the Pierce-Arrow wagon. None of the drivers is experienced with mechanical construction of machines and for this reason considerable outside attention is necessary, but this is done at the service stations of the makers of the vehicles. The truck and the wagon are not driven excessive mileage, 30 miles daily being a fair average, so it will be seen that both can be worked much more than they now are. During the summer, however, the truck will sometimes make two round trips, and the wagon will have a Warren run.

In winter the business is usually at its lowest ebb and the truck could be used for delivery and collection in Providence during the stay in the city, for the contracts with a number of stores for delivery necessitate a start later than might seem justified by other conditions. The circumstances under which the business was acquired and is now operated preclude a comparative statement relative to the economy of the machines, but the owner states that he is doing more work than when he assumed control and the business required 10

horses when he bought it. There is prospect of considerable development with the conclusion of winter, and it is not improbable that material changes will be made to enable the service to attract a larger patronage. The principal point is that the motor vehicles have opened the way for expansion, which would not have been practical with horses, and made a considerable gain despite very active competition from the stores and the public service corporations.

MAKING HIGHWAYS SAFE.

A bill is now pending in the Massachusetts legislature that was introduced by the Automobile Legal Association that is intended to establish the right of way of all vehicles using the highways, and to fix the responsibility for failure to observe the requirements of the regulation proposed. The bill provides that when persons travelling with carriages, wagons, carts, sleds, sleighs, bicycles, motor vehicles, motorcycles or other vehicles meet at the intersection of ways, where the traffic is not regulated by a policeman in uniform, those approaching from the right shall have right of way over those approaching from the left. All persons violating the requirements will be deemed prima facie negligent in any civil action against them for damage to property or injury to persons because of such negligence. Violation of the regulation is not a criminal offense, but in the event of civil action the burden of responsibility is placed upon those who fail to observe the provisions of the law. The bill has the indorsement of motoring organizations generally, and its passage will be strongly advocated.

DISTRIBUTE FILMS WITH TRUCKS.

The demand for moving picture attractions in the Metropolis and the desire of the theatres to give their patrons the latest productions has resulted in the formation of the Empire Service Corporation of New York City, which has purchased a 1000-pound GMC machine for the distribution of reels of film. That customers may have the same films the same afternoon or evening the reels are sent from one house to another and the machine is used for this work, being sent on a regular circuit. Thus the same reels may be seen successively at a number of theatres any afternoon or evening, a greater number being served than would be possible with any other manner of distribution.

BOSCH MAGNETO EFFICIENCY.

A Moline-Knight engine that was run for 336 hours continuously, the test ending Jan. 2, was equipped with a Bosch magneto and Bosch spark plugs, and in addition to the trial this equipment was used during preliminary tests, the horsepower and the five-hour economy trials without adjustment. During the 336-hour period of the demonstration 44,352,000 sparks

were generated by the magneto and 11,088,000 sparks passed across the gaps of the electrodes of the spark plugs, and the magneto contact breaker made 88,704,000 separate movements to produce the sparks. The result of the trial of the engine is regarded by the maker of the ignition equipment as proving the absolute efficiency of the system and its components.

SCIENTIFIC INDUSTRIAL HAULAGE.

The Edison Storage Battery Company, Orange, N. J., has published some exceedingly interesting literature relative to scientific management of industrial haulage, and naturally this has to do with the development of electrically operated facilities that may be substituted for steam, animal and manual power. One booklet is given over to internal transportation and the economies that are practical. The company emphasizes that it does not build trucks, tractors or locomotives, but places its data files, its engineers and experience at the service of managers who wish to minimize operating expenses, and similar assistance has been assured by the builders of equipment that may be utilized. Copies of this booklet, "Edison Storage Batteries for Industrial Trucks, Locomotives and Tractors", may be obtained by addressing the company.

REPAIRS FOR 14 MONTHS \$6.15.

A four-ton Peerless truck in the service of the Hartford, Conn., office of the Standard Oil Company, which was placed in commission in September, 1912, has been a remarkably economical machine. Though used six days a week for 15 months it was never withdrawn from work because of mechanical trouble or failure. Manager Freeman, who has supervision of the delivery, says that during the period named the entire repair bill for new parts was \$6.15, this including one fan belt, a short water hose connection and a half dozen grease cups. The truck has been driven more than 10,000 miles and is running very satisfactorily. The work accomplished with the machine was so pleasing that last June a three-ton Peerless chassis was bought and fitted with a tank for service from the Plainville station.

During the cessation of operations of the main plant of the Kissel Motor Car Company, Hartford, Wis., recently for the taking of the annual inventory and making repairs, a steam turbine with two 250 horsepower generators were added, this increasing the generating capacity from 1000 to 1500 horsepower.

Agitation has begun in Cleveland, O., for the enactment of a city ordinance that will require the use of fenders for motor service wagons, it being proposed to use the Detroit ordinance as a basis of the regulation to be submitted to the city council.

ONE TRUCK DOES WORK OF 25 HORSES.

Competition of Overland Freighting with Railroad and Express Company Between Providence, R. I., and Attleboro, Mass., Made Profitable by Use of Machine.

THE Peerless three-ton truck operated by Babcock's Attleboro & Providence express in public transportation between Attleboro, Mass., and Providence, R. I., is each day doing work for which 25 horses would be necessary. The truck is driven to a railroad-like schedule and the service has been so satisfactory to the business men of the town and city that the freight carried necessitates two regular and often three trips a day. The patronage has developed remarkably since the machine was placed in service, and while a comparatively small business the prospects are that it will continue to increase to much larger proportions.

Attleboro is 12.5 miles from Providence, and there are direct steam and electric railroad lines between the two, the running time for the former being 25 minutes and for the latter an hour. Attleboro has a population of about 18,000 and its principal industry is the manufacture of jewelry. Like many towns contiguous to Providence it has numerous small places of business, and the supplies for the factories and the shops and stores are generally purchased in Providence and Boston, and shipments must be made by railroad from either centre or hauled over the road. As Boston is 23.5 miles distant the steam and trolley freights and expresses are generally patronized, despite the fact that the rates are regarded as being very excessive. The shipments of jewelry, often valued at many thousands of dollars, are made daily by the express companies.

Railroad Rates Are High.

Though the Boston-Attleboro charges are large when the distance transported is considered, the rates for Attleboro-Providence shipments are even higher in comparison, and for this reason a considerable volume of freight is carried over the road. The Providence stores of first importance all make daily deliveries in Attleboro, and in a certain sense the town might be regarded as a suburb, but the stores of the town are representative and will compare with those of communities of similar size.

The main highway to Providence reaches the villages of Dodgeville and Hebronville, then passes through several sections of Pawtucket. The surfacing is excellent and the grades are comparatively slight. From

this aspect it would be difficult to find a route that was more promising for haulage, because of the possibilities for business between terminals and large loads that can be transported at what may be considered minimum expense.

The railroad and trolley passenger service, as well as the express facilities, are ample, the only reason for competition with this being the matter of rates, but the freight service is not only very slow, but the cost of handling at either end and the necessity of packing with the same care that would be desirable for shipment for 1000 miles, added to the high charges, is keenly felt by business men, who must fix their retail prices so that they can compete with the shops and stores of Providence. From every viewpoint the cost of stock and material must be kept at minimum, and while express shipments are at rates that include col-

The Three-Ton Peerless Truck Used for Overland Express Service Between Providence and Attleboro, Ready for a Load at the Providence Terminal.

lection and delivery the charges are such that freight is preferred where time is not a factor of importance.

Hard Work for Horses.

The conditions have impelled the patronage of men engaged in freight haulage over the highway, and for many years such businesses have existed, but while the distance is relatively short for railroad transportation the round trip requires hard work for men and animals. The experience has been with horses that there are few instances where the requirements are as severe. For instance, making a round trip would mean 25 or 26 miles without considering calls off the main route, and animals could not be driven this, hauling a load, oftener than alternate days, requiring two sets of animals, and an average freight of 3000 pounds would be as much as could be expected of a pair of horses.

Working horses the start must be made early in the morning and the return trip is not finished until late in the evening, and this means that the business men patronizing horse expresses must generally allow from 18 to 30 hours between giving an order in Providence and its receipt in their stores or shops.

These conditions were long endured by Attleboro men, and they were very willing to support any practical competition with the railroads and express companies, but the amount of money required to operate a successful service and the limitations of animals militated against those who engaged in this work. The express companies that engaged in this work were limited as to business because of the inability to compete with the railroads with reference to time, while the men owning them did not realize what they believed to be fair compensation for their work.

Saving with Motor Truck.

This was the condition when the service was owned by Edward Perry, who operated it for years, and it was considered to be the best of its kind. Mr. Perry purchased a Gramm two-ton truck about two years ago and with this began to improve the time of delivery and collection. With the truck the operating time could be greatly reduced, and the business men were able to get deliveries the same day as ordered. This was so decidedly an improvement that the truck was worked to its capacity, and the horse wagons were used for freight that was not as greatly needed, custom in a short time establishing practically two classifications of shipments. Shortly after purchasing the truck Mr. Perry died and the business was acquired by the present owner, who had been engaged in team haulage work nearly 40 years before.

Mr. Babcock had had long experience with horses and when he took the business he had ample opportunity to study the relative values of the animal and the motor vehicles. He had investigated the possibilities for development, and he did not hesitate to make such changes as common sense dictated. After working the truck and the horses side by side, over the same roads and doing practically the same work, he realized that the largest opportunity was in giving the business men along the route a service that would be faster than any other and at rates that would impel patronage.

He was not willing to accept theory and he depended upon the experience he could obtain from operating. He found that the business men were willing to give him all the freight that he could handle with his facilities. A tailboard delivery was tried out with the truck and when necessity demanded a single-horse wagon was used in Attleboro for collection and distribution, the truck and the horse teams being used for direct haulage. With the increase of business two trips were made with the truck, and to economize the time a single-horse wagon was placed in Providence to collect and deliver.

Mr. Babcock proved by experience the greater economy of the truck and believed that he would be

justified by eliminating the horses, and to do this a larger vehicle was necessary. In March, 1913, a Peerless three-ton truck was delivered to him and he disposed of the Gramm machine and the horses, and retained wagons that could be used with single horses at Providence and Attleboro. The new truck was a standard type with a large covered body that would carry large bulk, and with this a schedule was arranged that would best serve the business men.

The Daily Schedule.

Attleboro was the starting terminal and departure on the first trip was fixed at 7 in the morning, this permitting calls wherever necessary along the route and to take on freight that could not be handled from the horse wagon. All of the packages collected during the late afternoon and evening were loaded the night before and the chassis frame jacked to relieve the springs and tires from excess weight during the night. The in-bound route was made through South Attleboro, the Pleasant View section of Pawtucket, and from Main street square in that city to Providence the same as returning, but the return was made through the Darlington and Lebanon sections of Pawtucket, Hebronville and Dodgeville, covering a loop and serving all sections. The arrival at the Providence terminal was at 9, and with four men the freight was quickly removed and a fresh load put on, so that but 15 or 20 minutes was required to start the machine unless a delivery of heavy freight necessitated a separate call.

The outward trip required about two hours, stops being made for delivery en route, but on arrival at the Attleboro terminal the freight was removed and with the undelivered South Attleboro and a fresh load, which had been collected during the morning, the second trip was begun by 1:30. Four men handled the freight at this end and no time was lost, and the truck, as in the morning, had a crew of three, unless it was necessary to keep a second man in Attleboro to assist in the delivery. At South Attleboro delivery was made and freight taken on, and by 4 the Providence terminal was reached for the second time. The same routine was followed and by 4:15 the machine was ready for the return, and with the ordinary freightage the Attleboro terminal had delivery of the load from 6:30 to 7.

This description is of a day when two trips are made, but with a third trip the start is earlier and time economized wherever possible, so that the departures from Providence are at 9, 1:30 and 6:30, or thereabouts, and the Attleboro terminal is reached about 9, but the third load is only partly delivered at Providence, and is not distributed until the following morning at Attleboro, unless in the event of special need. In the event of the third load care is taken to make delivery of everything that is urgently required on the second trip, so as to insure delivery. With two trips, practically every package is delivered the same day as shipped, though South Attleboro freight from Providence is generally held over night in Attleboro.

Results That Are Obtained.

The Attleboro man who delivers an order in Providence by mail or telephone can receive the goods practically at noon if the package is sent to the Providence terminal or notice given for its collection up to 9 in the morning. Or he can supply a customer early in the evening from an order given as late as 3:45 in the afternoon. Shipments can be made to Providence with equally good service, and so the overland express is carrying practically capacity loads the entire mileage driven, which ranges from 50 to 75 a day. Three trips are made about half the time, although Saturdays only one is the rule, because of the early closing of the shops and factories. The average weekly mileage will approximate 300 miles, and frequently 325, and the tonnage will reach, if not exceed, three tons to the trip.

Mr. Babcock pays excellent wages and expects his men to earn them. The driver had more than six years' experience with automobile vehicles before he started to drive the Peerless truck, and of that time three years was in repair and garage work, so he does practically all that is required to keep the machine in high class condition. When necessary he works nights, and every Saturday afternoon the truck is gone over carefully and adjustments made, so that it is always kept in excellent condition. He is expected to keep the machine operative, and thus far not a trip has been missed. Not only this, he drives with extreme care, and this means a great deal so far as wear is concerned.

Speaking of the work done by the truck, Mr. Babcock says that when used for two trips a day it is doing the work that would require 25 horses, and with animals the start would be at 5 and the finish for the day at 10 at night, and when three trips are made the truck saves at least three hours of the time that would be necessary with but a single trip for animals. So far as the business men are concerned they have service that is faster than the average expressage, and the prices charged are lower. The business has increased constantly, and it has reached such proportions that another truck will be added in the spring to take care of freight from sources that have not as yet been developed, but which have promise of yielding a tonnage that will equal that now carried.

WHAT IS A COMMERCIAL VEHICLE?

The commercial vehicle committee of the National Automobile Chamber of Commerce has adopted the following definition of the term "commercial vehicle":

A commercial motor vehicle is a self-propelled vehicle designed to be operated without rails for the primary purpose of transporting materials, products, passengers or apparatus especially for business purposes or for hire, profit, emergency work, or special utility service as distinguished from private personal use by the owner or renter for enjoyment or convenience.

The reason for this differentiation was the decision of manufacturers to restrict the annual exhibitions at New York and Chicago to passenger vehicles, this necessitating a definite determination as to what vehi-

cles could and could not be displayed. As defined by the committee all machines are excluded that are not primarily designed by the manufacturer for industrial or commercial purposes, so that a taxicab station wagon or stage, used for private passenger conveyance by the owner, is classified by the purpose of the builder. Fire apparatus is included in this class, but fire chiefs' cars, being pleasure car chassis fitted with special bodies and used for special purposes, are rated with the passenger car class. Converted pleasure cars are rated as passenger vehicles, although officially registered in the other class. It will be understood that the decision, while primarily adopted to benefit the show committee, will be undoubtedly accepted for the classification of all motor vehicles of American production.

TRUCK EARNS COST IN 10 MONTHS.

The cost of a White truck in the service of the sanitary department of Atlanta, Ga., was earned by the machine in 10 months, during which time it was driven an average of 30 miles daily, making a total mileage of 7800, carrying 18.4 tons daily and a total tonnage of 4784. The truck is used for transporting refuse from the business section of the city to an incinerating plant and does work for which 12 mules, 12 single carts and 12 drivers were necessary. The operating and maintenance cost of the animal equipment was about \$600 a month, and the average expense for operating the truck was less than \$200 a month, including the cost of a helper, whose pay was figured in the operative expense of the mule carts. The economy of the machine was so great that the department has purchased two more trucks.

BRACKETT SUCCEEDS MORRIS.

M. E. Brackett is now manager of the New England branch of the General Motors Truck Company, succeeding J. L. Morris, resigned, and in charge of the business at the headquarters of the company at Boston. Mr. Brackett was travelling representative for the general manager and sales manager of the company before his appointment, and in that capacity visited all parts of the country. He has been connected with the industry for eight years and has intimate knowledge of every detail of the business from production to selling. Mr. Brackett proposes to inaugurate a vigorous selling campaign in New England for the GMC gasoline and electric service wagons and trucks.

The Wagenhals Motor Car Company, Detroit, has appointed L. B. Sanders manager of its sales department.

The tentative dates for the mid-summer meeting of the Society of Automobile Engineers are June 22-27, and the place will be Cape May, N. J.

ELECTRIC DELIVERY SERVICE.

Company Formed at Cleveland, O., to Distribute the Sales of Many Stores.

Beginning with 25 Baker electric wagons ranging from 1000 to 8000 pounds capacity, and three gasoline trucks, the Delivery Company has inaugurated a service at Cleveland, O., which is expected to be developed to large proportions. The company was organized by Cleveland men who purpose to afford to the merchants of that city facilities for distribution that are superior to what had previously obtained, and which will insure a large measure of efficiency at prices that are more economical than could be realized from separately operated equipment.

The company expects to add to its vehicles as needs are developed, and if the service is increased as the promoters of the company believe it will be, there will be 75 electrics in use before the end of the present year. The company makes contract to furnish vehicles of any desired capacity and any type body, bearing the names of the firms using them, for a stated cost, but where the machines are specially equipped and ornamented for a business house, contract is for a year, the price including the wages of the driver and every expense, and varying with the size. About half of the vehicles are rented in this manner. The remainder of the wagons are used for the delivery of merchandise and packages of all kinds, the charge being based on the size of the unit and the distance to be carried.

Thus for a contract price the firm may have a vehicle of any class constantly at its command, or it may have the work done on the unit basis and pay for this work at stated intervals. The company has already made contract with about 175 business houses and this number will, no doubt, be increased as rapidly as the service is demonstrated. The company began business in November and during that month the machines were driven an average of 41 miles daily and delivered an average of 181 packages. During December these

averages of number and mileage were considerably increased.

The company is now building a station that will include its offices, receiving and shipping departments and garage in East 21st street, which ought to be ready for occupancy Feb. 1, and meantime it is using a rented store for receiving and shipping and the machines are housed in a convenient garage. The station will be 100 by 140 feet and will have garaging facilities for 75 vehicles, and it will have equipment intended to afford the greatest economy of time and labor in every department.

The sales from the different stores that have the contract delivery by package or unit are collected and taken to the receiving station, where they are sorted for routes and then arranged in the wagons for distribution. The necessity of minimizing every work in connection with the delivery is evident. With the garage the purpose is to have sufficient storage space for all the machines that shall be used, with facilities for giving such care and attention as may be necessary, but because practically all of the wagons are electric and the factory of the builder is in Cleveland, shop and tool equipments are much smaller than might otherwise be needed. The gasoline trucks are used for long distance hauls to suburban points and reasonable provision is made for caring for these, but the company does not expect to add to this number unless the service is considerably extended.

The company is well financed and equipped, and the system for distribution has been carefully developed. It is prepared to undertake any work and to guarantee that the service will be uniformly good and that all patrons will be equally well served.

A tractor designed for use with trailers in general highway transportation is to be built by the Detroit Wagon Works, Detroit, and will shortly be produced commercially.

The 1914 session of the American Road Congress will take place at Atlanta, Ga., the week of Oct. 19-26.

The Vehicle Equipment of the Delivery Company, Cleveland, O., Consisting of 25 Baker Electric Machines and Three Gasoline Trucks, Used for Merchandise Distribution for Stores of That City.

LONG DISTANCE ROAD HAULAGE.

Possibilities for the Development of Freight Transportation by Highway Vehicles Between Commercial Centres in Competition with Railroad Lines.

THE productiveness of transportation equipment depends entirely upon the loads carried. If the freight is the same during the haul and is to the capacity of the vehicle the other factors to be considered are speed, haulage conditions, loading and unloading facilities, and administration, which may be said to include operation, care and maintenance. Turning to production, with the average service, the load may be safely assumed to be carried practically 45 per cent. of the distance traversed, the remainder being empty or "dead" haulage. This means that the earning power of such equipment is limited to 45 per cent. of the possibilities were a full load carried. The greater the percentage of loaded haulage the less the cost, no matter what unit of measurement may be used.

Usually the result is expressed in weight or number of packages of standard size.

No one will question the fact that with horses the maximum mileage possible is from 15 to 20 daily, and accepting 10 hours as the working time of a day this will permit movement at a speed of from three to four hours half the time, and the other half is of necessity idle time, which can be given over to loading or unloading without encroaching upon the working period. The animal is limited in speed and physical capacity. The conditions of use are such that under the most favorable circumstances it is impossible to consider them for any distance beyond 10 miles for regular haulage, although this may be considerably increased for occasional service or where the work is a straight haul in one direction.

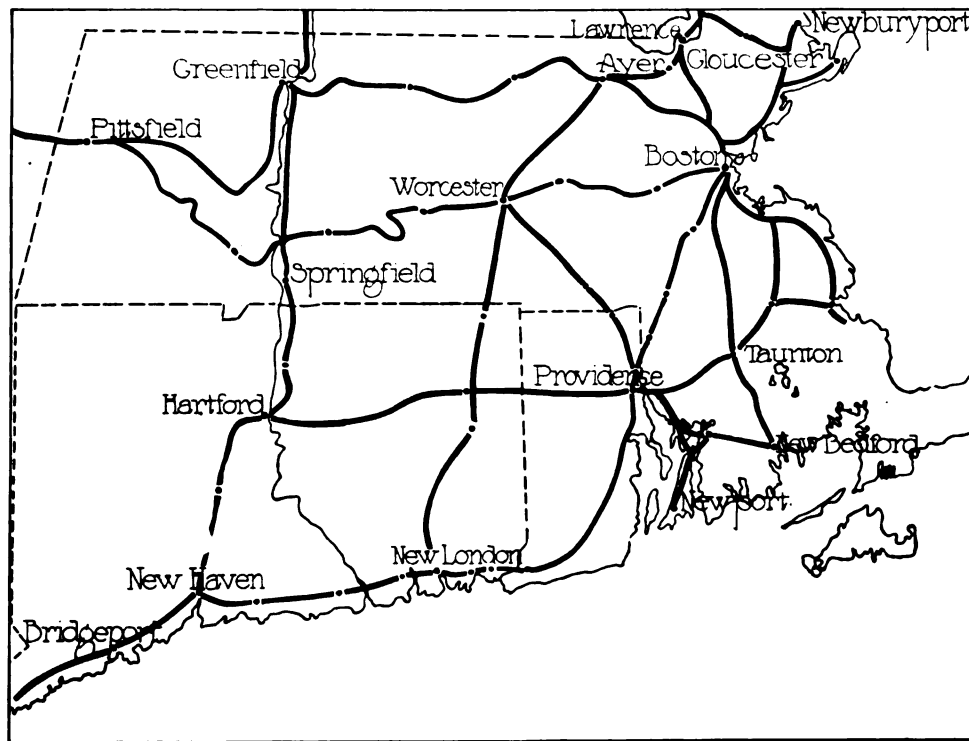

Long Hauls Most Economical.

The long haul is always the most economical, no matter what the form of transportation, and this ap-

plies to road vehicles quite as well as to railroads or vessels. There is, however, greater probability of return freight with the transports of common carrying enterprises, and the development of these depends very largely upon the service that can be afforded in either direction. Where a transportation department is maintained by an industrial or commercial concern, it is not often available for others, and usually it is not largely in excess of normal requirements. The policy generally is to have what equipment will be sufficient for ordinary purposes, for this can be at times worked beyond capacity when necessity arises.

The economy of any form of transportation is dependent upon two factors, the one being time and the other the lowest expense. Where time is not mate-

rial and freight can be delayed to practically any extent without affecting business, then it may be carried at convenience and in such manner as will be at minimum of expense. But where time is valuable and business transactions are dependent upon expedition, then speed is required proportionate to the need. The

Map of New England Showing the Main Highway Connections Between Commercial Centres That Could Be Terminals for Motor Truck Haulage, with Established Service to Points Beyond the Regular Routes.

point of demarcation where economy of time and economy of cost are equal in value to the business man must necessarily vary with each individual transaction, and so it is impossible to establish either as a constant. This being so, the determination of the individual must be accepted.

With every transportation proposition so many variables must be considered that rules can hardly be applied, and while principles may be followed generally results are very largely governed by proportions, the administration of the large concerns usually being the better and consequently the more efficient.

Considering motor vehicle haulage, there are those

who believe that machines are not economical for work within a radius of five miles or less, and that the fullest value is not realized until the average haul is at least that distance. But while there may be question as to the exact point in distance where in productiveness the motor wagon is superior to the animal conveyance, there is no doubt that beyond that point every factor contributes to the advantage of the former, and this increases to another point where the railroad or water lines become in turn more economical than the motor wagon. It is obvious that with any form of transportation the cost decreases with the increase of capacity.

What has been stated with relation to doubt as to the economy of the motor wagon or truck is applied to what may be regarded as the short hauls, but where haulage may be systematized between two points it is entirely practical for freight to be carried for considerable distances, as far as 50 miles, and distributed with saving as compared with either freight or express service. It is certain enough that if the haulage can be in either direction between points the productiveness may cover the entire distance, or a very large percentage of the capacity may be carried for every mile travelled while in regular use. That is to say, that a start may be made from one terminal with a load and this lessened by deliveries along the route to the other terminal, and the return made with similar distribution. This may give an average of from 50 to 75 per cent. of the route, which is largely in excess of the average productiveness of the machine that is productive less than half the mileage traversed.

The volume of industrial and commercial products transported by highway is comparatively small, and in sections where the business centres are short distances apart, as in New England and the eastern states especially, the conditions are unusually favorable for the establishment of motor vehicle service which will have all of the advantages of long and constantly productive hauls. There are many reasons why such means of transportation should be profitable.

Railroad and Trolley Service.

Considering the railroads for a moment: First the rates for freight carrying have for years steadily increased and, with the greater operating cost, the companies have been compelled to exact what may be regarded as excessive charges. Despite the increase of rates the service has not improved and there is less efficiency than when competition impelled expedition in handling and minimum charges. Those who have expert knowledge of railroad transportation say without hesitancy that the cost will never be less save through some remarkable change that cannot be anticipated, and which will probably not long endure. In fact this condition may be applied to all forms of transportation, and with labor unions forcing increased wages and capital demanding reasonable return on investment the probabilities are that the railroads will bring about the establishment of rates materially larger.

The trolley lines have been established mainly for

the transportation of passengers and the haulage of freight is incidental. Some of the companies, where it is possible to make satisfactory traffic arrangements, have inaugurated service which will reach sections more or less limited, and these have differing classifications, one where the goods are delivered at one terminal and on arrival at another the consignee is notified to call at convenience; the second where the goods are collected by the company and carried, and similar notification given, and the third where the goods are collected, transported and delivered, the three affording what may be termed fast freight, limited express and full express. Service of this character is not general throughout the country, and where express service is specialized this means the maintenance of highway vehicles for collection and delivery.

Besides this there are the express services of the large and the small companies, some being identified with railroads, others carrying goods on railroads, while many afford transportation between different places by vehicle. There are hundreds of commercial centres that are from 25 to 50 miles apart, and with towns, cities and villages between them on direct lines of highway communication, so that with two terminals it would be possible for service to be given in either direction at such intervals as would be justified by patronage.

Highway Transportation Possibilities.

If the possibilities of highway transportation are to be realized it will be necessary for those engaging in it to develop such affiliations as will be productive, and this means that it would be practical for transfer of goods to be made from the one company to another under a traffic agreement that would be mutually satisfactory. Mileage might be the measure on which the inter-company business could be handled. There are many suggestions that might be developed and adapted, the one object being to divide the revenue so that each would be equitably compensated for the service. Exchange of business is common enough with express companies, but the idea as stated is merely to illustrate the possibilities that might be developed by unity and a section of considerable size served with economy to the public and profit to the concerns engaging in it. That is to say, that instead of each being an independent service an exchange would bring about a relation that would be profitable and would be shared by all. Such an exchange could be furthered by a central receiving station, which would virtually be a clearing house for all companies, and this could be maintained at small expense by a number, each contributing, proportionately or on any basis that might be equitable.

Companies operating on main routes might in turn have affiliations with those serving smaller communities, and it would be practical for all services having routes of considerable length to utilize motor equipment. There are hundreds of small services that could in this manner be developed, and with the rates the same as those of the railroads or the other companies

There is no question of patronage, from the fact that deliveries and collections could be made, this being a factor of considerable importance. From the viewpoint of the practical business man there would be many reasons why such service would receive favor. From each commercial centre routes could be established that would serve varying sections, and with many available merchants and shopkeepers, particularly those who purchase in small volume, but frequently, could be able to have stock sent in whatever quantity at any time desired.

Opportunity for Patronage.

As a matter of fact large population is not the only factor to justify the establishment of motor vehicle transportation service. Undoubtedly the patronage would be larger in communities of considerable size, but the possibilities of developing contract haulage with manufacturing firms, stores, etc., ought to be exceedingly attractive. Such business could be established on a very dependable basis, for traffic of that character would be constant, and without question a considerable volume of haulage could also be secured. Indeed, of course, that there was assurance of satisfactory service.

Considering any of the present forms of transportation there is reason to believe that the charges will continue to increase. The parcel post is limited to packages of 20 pounds or less, and with long hauls and increased productive mileage the motor vehicle transportation company with reasonable administration can easily be operated so as to be profitable. By that is meant that the motor truck can today be used for those places where its economy is known, and that there are thousands of conditions where it will not only be efficient, but it will be possible to develop business through the lower rates that can be made for haulage. The East has seemingly better opportunities for highway transportation than the West, for the commercial centres are more numerous, the topography of the country is more favorable for highway haulage, the roads are generally more improved. Many of the state systems of roads have been developed to considerable proportions, and as the main thoroughfares connecting the cities are always given attention and are better maintained, the conditions for development of road transportation are constantly becoming more promising.

Deciding Upon Rates.

While it is true that the weight of freights that can be carried on road vehicles is limited to capacity, this limitation obtains with reference to any other form of conveyance utilized, and the rates are based on the cost of operation. Long daily mileage means, naturally, that the operating expense will be relatively high when with shorter routes, but if the service means collection and delivery, thus reducing or eliminating the need of the customers maintaining vehicular equipment, the rates can be based on something more than those charged by railroads or water lines.

To illustrate: The railroad could haul five tons 40

miles at a very low rate if the contract were for large tonnage, but it would necessarily charge a lower rate if the haul were longer. Motor vehicle haulage would be usually of small packages, or those which would be small for railroad or water transportation, for which an entirely different classification is made, and the rates for these, including collection and delivery, could be based on the economy that the customer would realize. Usually railroads connect the commercial centres, and while there would be no possibility of motor trucks competing with them in the haulage of large tonnage, a large volume of the packages sent and received could be carried.

The distribution at the terminals of each service could be whatever afforded the greatest satisfaction and was the least expensive. Were the exchange or transfer system the vogue this would afford transportation to points beyond, while local delivery could be done by the same organization or by others. In cities of considerable size the deliveries from business houses to customers in suburban points is constantly increasing, and as the majority of firms seldom serve their patrons at a greater distance than 10 miles, other means of conveyance are utilized, these being either freight, express or parcel post, that being chosen which is least expensive, or which will meet requirements when the demand of the customer is known. Where time is limited the cost is greater. Such service as can be provided with motor vehicles ought to attract a considerable volume of such patronage.

MOORE MOTOR TRUCK COMPANY.

The Moore Motor Truck Company, organized at Philadelphia, Penn., has located at Wilmington, Del., where a building at Buttonwood and C streets has been leased with a guarantee of purchase within six months. The installation of machinery has been completed and the company is now ready for production. A wing 200 by 60 feet will be added to the plant. The company will employ about 75 men at the start and expects to build about 350 machines the first year. The machine will be built in one size, having 3000 pounds capacity, and is said to be a highly perfected type of vehicle.

The officers of the company are: President, Thomas E. Moore, formerly vice president and general manager of the Bowling Green Motor Car Company, Bowling Green, O.; vice president, Samuel L. Dillon, Wilmington; treasurer, Frank B. Adams, Pittsburg, Penn.; secretary and assistant treasurer, George W. Brewer, Philadelphia; sales manager, C. L. Dambley, Philadelphia.

A new factory, 100 by 500 feet, is now occupied by the F. L. Moore Truck Company, Torrance, Cal., and about 125 men are now employed. The plant, when operated to its capacity, can turn out approximately 1000 machines annually.

MOTOR TRUCK SAVES HALF OF HORSE COST.

THERE are those who believe that the motor service vehicle is best utilized over roads that are smooth and level, where the loads can be handled quickly, and where the hauls can be made with comparative speed, for these conditions would appear to be most favorable, and yet where the requirements are directly opposed to those stated, remarkable efficiency has been realized. One factor will always govern the real productiveness of a transport, and that is the value of the load carried, for on this depends the earning capacity of the unit, whatever it may be. For this reason, where the freight has small valuation, the rate that can be charged for it, necessarily proportionate, minimizes earning capacity.

Trucks have not been generally utilized in lumbering because of the great difficulty of getting to and from the logging camps, and as logs are floated down rivers and streams wherever practical the mills are located close to railroads when possible. In some instances, however, owners of timber land have erected mills close to the camps and haul the manufactured lumber to the most convenient shipping terminal. Not many years since the largest timber cutting operations were in the eastern states, but each year the supply of standing wood has diminished and now the Northwest is being heavily drawn upon. On the Pacific Coast the lumber cutters have cleared vast areas and very frequently they have found the greatest economy in establishing mills and hauling the manufactured lumber

to shipping points. With each year's cutting the distances increase, and, of course, there is a limit as to what can be done with animals. This condition is very certain to result in the utilization of motor trucks and tractors, or the building of industrial railroads, and of these the former appears to be the most satisfactory, despite the labor of building roads.

Logging roads, however, mean mere paths from which the rocks and stumps have been cleared and bridges built where streams and ravines are to be crossed. Filling is merely bringing the surface to height that can be traversed, and during the thawing periods of the spring corduroy is regarded as sufficient to insure the trails being passable. Road making in forest, where the soil is largely deposits of decayed vegetation, where removal of stumps and rock entail filling, and where drainage cannot be promoted, is indeed difficult. Grading, to secure level and even surfacing, is often impossible.

Naturally, the operation of any vehicle over logging roads is slow and more or less dangerous because of the paths following the natural contour of the ground, and winding like a snake track to clear the largest obstacles. The difficulty of obtaining traction in climbing and of braking when descending grades is always to be considered, and in wet weather a road of this character will be churned into deep ruts and mud holes that generally mean smaller loads and more time for haulage, and sometimes becomes almost impassable.

Hauling Shingles in the Mountains of the Northwest: A, Typical Mudhole in the Trail; B, Crossing a Stream on a Log Bridge; C, Where the Going Is Good; D, Passing a Ravine in the Steep Grade; E, Level and Straight, but—; F, Where the Road Is Even Lacking.

A condition that can be better realized from the accompanying illustrations than from description, obtains in the use of the two-ton Garford truck owned by the Drury & Brown Shingle Company, which operates a shingle mill high on the side of a mountain 18 miles from the village of Sequim, Wash., which is the nearest point of railroad shipment. The timber suitable for manufacturing would necessarily be hauled were the mill located in the village, and this would mean the expense of transporting that wasted in milling, which would add materially to the cost, and so the best solution appeared to be hauling the bundles ready for shipment rather than the logs.

To ship the shingles a road was constructed that, despite the need of economy, was very costly. Some of the grades are 20 per cent. and for two-thirds of the distance the path is extremely rough. Several log bridges cross streams and brooks, and these are usually a few long logs with a corduroy of timber spiked to them. There are several sections of sand, a great deal of loam, a long succession of mud holes, and in one place the road is in a sandy bed of what was once a mountain stream. The road gradually ascends nearly to the line of perpetual snow, so that there is practically a constant climb when the machine is going to the mill, and a general descent when taking out the loads.

The shipping weight of a bundle of shingles is approximately 50 pounds, and loads such as are shown in the illustrations range from 100 to 120 bundles, so that 6000 pounds, or slightly in excess of that figure, will probably be a fair average of a freight. The truck makes two round trips each day, covering a distance of about 72 miles, and the cost of haulage has been reduced more than 50 per cent. as compared with horse work. The machine has now been in service for eight months and has not missed a trip.

The Sternberg Motor Truck Company of New York is now established in a new service station at 12th avenue and 123rd street. The lower floor is used for garaging and the upper floor for service purposes. The station will store about 125 machines.

The factory of the Firestone Tire & Rubber Company, Akron, O., is being increased 40 per cent. in capacity by the construction of two wings to the main structure. These are of reinforced concrete and will be ready for operating early in the spring.

A new factory for the plant of the Timken-Detroit Axle Company, Detroit, Mich., is projected and will probably be erected in the spring.

A building 30 by 90 feet, one story, will shortly be added to the plant of the D'Arcy Spring Company, Kalamazoo, Mich.

During 1913 approximately 13,000 motor wagons and trucks were registered in New York State.

WHERE TRUCK IS ECONOMICAL.

Some Examples of Work with Two-Ton Kissel Machine That Show Profits.

H. R. Oglesby of Springfield, Mo., the owner of a two-ton KisselKar machine, has from experience realized that the real productiveness of a motor service wagon is keeping it moving, and that the economy of time is as practical in the short haul as in the long, although the actual mileage of either class of work may differ very much. That this statement may be clearly understood one may regard one as a continuous run, and the other as a number of trips between points not far distant. With the first the time necessary for loading and unloading is but a small part of the aggregate in service, but without a return load the work is really less than half the time engaged. With the last the time of loading and unloading is relatively greater, but with sufficient help the truck could be kept on the road a great deal more than might be assumed was possible, and there would be a decided gain in efficiency when contrasted with work done with other vehicles.

These statements are borne out by some of the experiences of Mr. Oglesby, whose longest trip was from Springfield to Buffalo, Mo., a distance of 40 miles, carrying 4680 pounds of oil. The distance was not excessive, but the road is through the Ozark mountains, traversing a very rough country and at one point a 40 per cent. grade is met. This has usually been an obstacle that other trucks could not climb.

In contrast with this is given the work of a trip of 12 miles, making 19 stops and delivering a load en route, the time required being one hour and 35 minutes. The time required for this work with two horses was four hours. Still another was a trip of 10 miles, carrying 5500 pounds of freight and delivering it in 17 stops in one hour and 40 minutes. With a team of horses from 3.5 to four hours were necessary. One of the best showings made was when 40,000 pounds of potatoes were unloaded from a car, hauled 10 blocks and placed in a store basement, inside of two hours. With this work two helpers were employed and the loading and unloading was rushed. The machine is driven from six to eight miles to the gallon of fuel and from 40 to 50 miles to the gallon of lubricant.

Ten machines a month in 1000, 2000, 6000 and 10,000 pounds capacities will be built by the Utah Motor Truck Company, Salt Lake City, Utah, which recently began commercial production of these vehicles. The name adopted is the Utah.

The announcement was made at the dealers' convention at the factory of the Baker Motor Vehicle Company, Cleveland, O., that the sales of trucks had increased 130 per cent. in the year preceding this present gathering.

WORLD'S MARKET FOR MOTOR TRUCKS.

Conditions Which Must Be Met in Order to Secure Export Business--Possibilities for Sales in the Several Sections---The New Tariff and Its Effect on Imports.

WHILE complete information as to the exportation of automobiles during 1913 is not yet available, and probably will not be for at least two months, the report of the Department of Commerce for the first 10 months indicates that the total valuation will be not far from \$28,000,000, of which nearly \$2,000,000 will be represented by commercial vehicles. An accompanying table presents the exact figures for both commercial and vehicles shipped to individual countries during the governmental fiscal year ending June 30, 1913. This shows a total valuation of \$26,012,934, of which \$1,737,141 was represented by business wagons.

These figures are of decided interest to the automobile industry, and when considered from the viewpoint of the entire industry are indicative of a most wonderful growth. It is hardly more than 17 years since the first self-propelled road vehicle was imported into this country by Kenneth Skinner of Boston. During

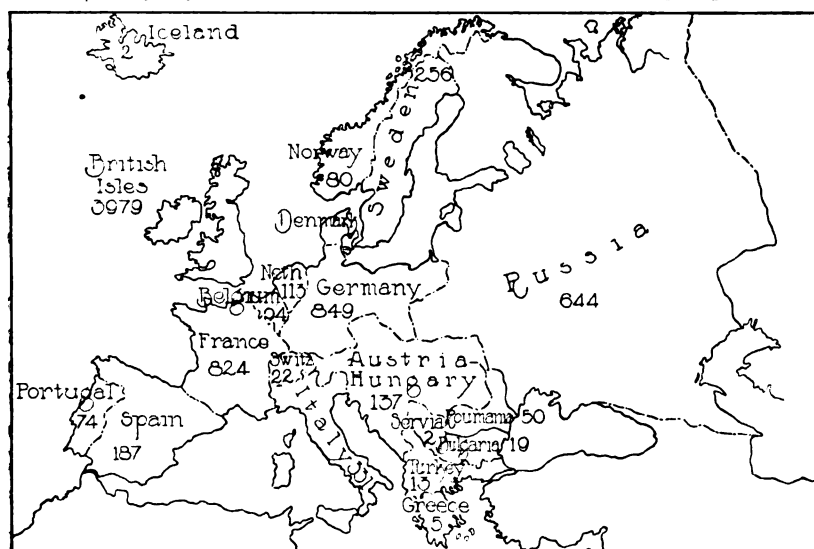

give them the required assistance in this respect.

Where an attempt is made to do business direct with the dealer in a foreign country, it usually becomes a question of receiving the cash before the goods are shipped. This has its disadvantages, because the dealer may have difficulty in securing the ready money, either to establish a drawing account in America or to pay for each car when ordered. As a result the sale of machines is retarded.

Extension of Credit.

When the manufacturer is able to be represented abroad by a direct factory branch or through a subsidiary export company, the matter of extending credit to the dealer is assumed by these. This does not materially change the conditions, however, except insofar as the foreign representative has more ready access to the sources of information concerning the applicant for credit. When the dealer is located at a substantial distance from the branch or exporting company, the same general rule applies as when he seeks to do business with the factory direct.

In doing business with an outside export house, the factory deals with that house alone. The latter is free to extend credit or demand cash, as the case may be, and it is stated that the same rule, of cash before delivery, usually applies in this instance. The export house has the advantage of dealing in a wide variety of articles—practically everything that is produced in America—and is in a position, through its confidential agents in the several commercial centres, to make its own terms with the local dealer. It follows that the general rule is to pay cash for the car upon delivery in New York,

Map of Europe, Showing Number of Cars Shipped to Each Country.

the first 10 months of 1913 the total imports aggregated \$983,445, as against \$1,573,584 for the same period in 1912 and \$1,657,281 during the same months in 1911. Something more, with reference to the imports, will be said later, but the chief purpose of this discussion is to present some of the conditions entering into the matter of exports.

How Business Is Transacted.

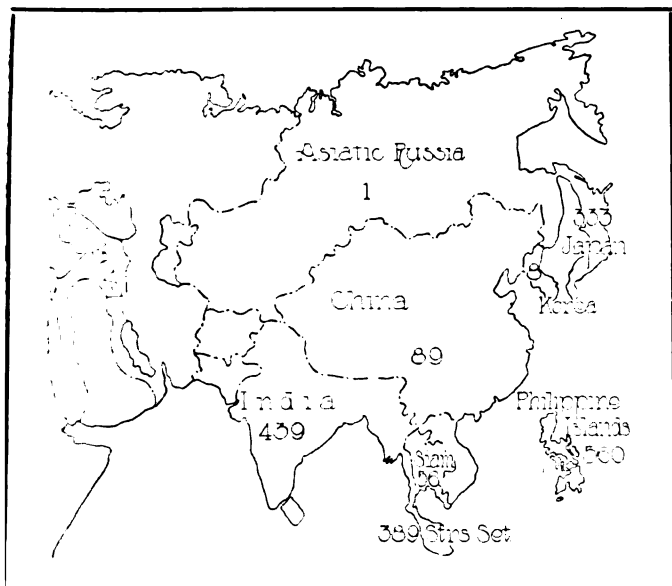

In the first place, it may be stated that the exportation of \$28,000,000 worth of automobiles is not brought about without careful attention to details. Some manufacturers maintain direct factory branches in certain foreign countries from which the cars are reshipped to their destination. Others have formed separate exporting companies in this country. A few do business direct, while a majority look to the export houses on the Atlantic and Pacific Coasts to

Philadelphia, Seattle, San Francisco or other port, and either extend credit or demand cash from the dealer as the circumstances appear to warrant from the knowledge of the situation supplied by its representatives.

Necessary Expenses of Exportation Methods.

Only one condition has been considered in the above. Obviously the exportation of one or a number of cars is not without expense to the manufacturer. When business is done through an export house the car is sold by the manufacturer at the regular dealer's price, at which price, plus the freight, and the duty if any, it is resold to the dealer in the foreign country. The export house secures its remuneration from a commission on the sale, paid by the manufacturer.

It may readily be understood that the expense of maintaining a factory branch in a foreign country is

How Cars Were Distributed in Asia.

considerable, although it may be conceded, at least for the sake of argument, that some of this might be passed along to the dealer. The subsidiary export company also has its expenses, and much the same may be said concerning these. In dealing direct, the cost of securing business is governed very largely by the manufacturer himself, and may be much or little as the possibilities seem to indicate is desirable.

Existing Market Conditions.

For the purpose of securing reliable information concerning the world's markets for automobiles, the writer recently interviewed a number of men who are in close touch with the actual conditions in various world centres. These included representatives of export houses, who either have just returned from the country in question or were in receipt of recent reports from their confidential agents in the field. Some of them have been exporting automobiles since 1902, and are still making periodical business trips into sections of the globe concerning which few Americans are at all familiar, even as tourists. There can be little doubt that the resume which follows presents actual conditions as they exist in the several countries.

Situation in Europe.

Insofar as the European market is concerned, the demand for American made commercial motor vehicles must be limited very largely to Russia, and the so-called Balkan States. In Great Britain, France, Germany, Italy, Switzerland, and some of the other nations, in which the industry is well represented by manufacturers, the home product is almost invariably considered by business men to the exclusion of all others. American manufacturers will find that these concerns are not only strong competitors at home, but in other parts of the world, notably Asia and South America.

The Spanish government makes every effort to encourage home industry, and this is also true of the Italian government. Spanish business men are strongly inclined to follow the example of the government,

and when they fail to find that which they need at home, they usually prefer to do business with Continental concerns. The reason for this lies in the ready accessibility of these factories in the event of need for repair parts, etc. Portugal is still further handicapped by what is considered an excessive freight rate from New York.

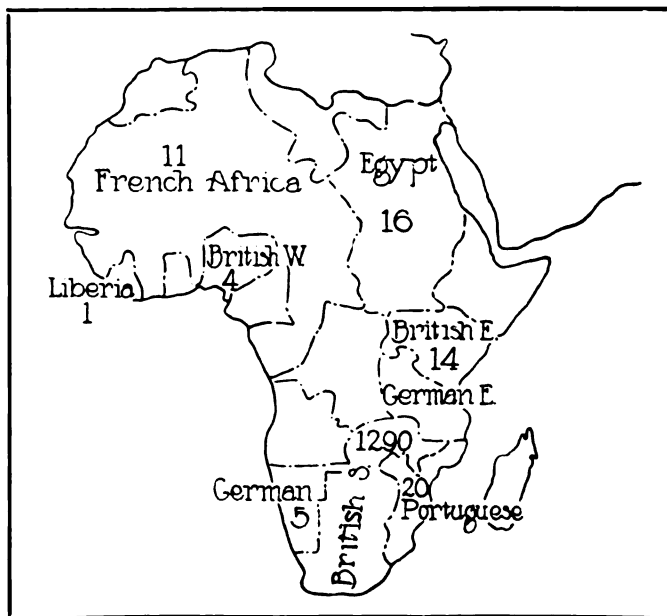

Russia and Balkan States.

The countries of northern Europe, with the exception of Russia, have not become intensely interested in commercial motors as yet, and it is only within the past year or two that they have been purchasing pleasure cars in any great numbers. Even in that field it is the low price of the machine which attracts them to the American product as yet. The Russian government has had excellent success with motor trucks of American manufacture and for this reason such business men as are interested are seeking information concerning these. There appears to be little probability that there will be any decided competition from Russian made machines, at least for the present, since business men receive little financial encouragement to form companies of this character. The road conditions are far from ideal in many sections, particularly in the interior.

The situation with regard to the Balkan States is somewhat problematical as yet, although the successful use of both pleasure and commercial vehicles during the recent Balkan war has had an appreciable effect upon the sale of cars, in that it served to direct attention to the merits of motor vehicles for various purposes. The market undoubtedly will see a number of changes within the next few years.

Asia and the Orient.

In Asia, probably the best market for motor trucks at present is in Siam. Ten per cent. of the total automobiles owned in that country are commercial vehicles. This is due to some extent to the fact that the field has been worked in a systematic manner, largely

American Cars Exported to African States.

by representatives of French manufacturers, who have specialized in motor trucks wherever possible. Many of the so-called native houses are owned by wealthy Chinese, and these are quick to appreciate the advantages of this type of vehicle. Many of the machines are with rated capacity of three and five tons. The greatest handicap for the American manufacturer is the length of time required to secure spare parts, unless some arrangement can be made to locate a spare parts depot within easy access, and it is advisable to have a man on the ground who thoroughly understands the mechanism of the truck.

The Straits Settlements have purchased a number of American cars, and a few American trucks. British motoring prints have suggested repeatedly that this was an excellent market. While it undoubtedly is true that motor trucks would be of invaluable service to the planters and that they could be made to appre-

ple in automobiles. The government is not in a prosperous condition, and this has a decided effect upon business generally, as financial operations depend somewhat largely upon the government's expenditures for internal-improvements, etc. The roads are narrow and must be rebuilt for automobile use in some instances.

China is looked upon as a favorable market, but business conditions cannot be regarded as settled just now. It is probably true that such Chinese as are able to afford machines will be more kindly disposed toward them under the new regime. The scarcity of roads of any description worthy the name will influence their sale in many sections, however.

The Philippines, although under the protection of the American government, are considered as a part of the Orient. It is considered by many that the American government made a mistake in first procuring commercial vehicles of French manufacture, but this has now been remedied, so far as that is possible, and the market for American made motor trucks is held to be very promising.

Situation in South America.

The importance of South America as a market for automobiles of all types is only partially understood by the residents of the United States. Opinions regarding the people of Latin America have undergone a decided change within the past few years. This applies more particularly to the automobile industry, but it has its application to every line. The country is rich in natural resources, and many large cities have grown up along the coast. The people are accustomed to buying the best.

Contrary to the accepted view in the United States, the Latin Americans have no political feeling against this republic—at least, any feeling that they may have is not such as to interfere with commercial intercourse. There is a belief among them, however, that whenever they desire to purchase the best they must go to Europe for it, not because high grade products are not manufactured in this country, but because South America never sees them. They maintain that when they order such goods from America they invariably receive poor treatment.

Why Development Was Retarded.

Numerous examples are cited to bear out the assertion that the United States considers South America a suitable dumping ground for goods that are entirely unsalable in this country. The development of the automobile market in Brazil, Argentina, Chile, etc., undoubtedly was delayed much longer than necessary by the fact that certain concerns failed to realize the importance of the initial orders.

One case will prove sufficient to illustrate the point. A well-to-do Brazilian was visiting in New York City and had opportunity to judge of the merits of a high grade American car. Before returning home he placed an order for one of these machines, paying some \$8500 in cash. When the car arrived in Brazil it was found to be minus certain parts essential to its

Indicating the Market in South America.

ciate this view of the situation, the present price of rubber probably will have the effect of postponing action until the financial condition improves.

There is held to be a satisfactory market for a limited number of machines in India, although it must be remembered that the percentage of people in that country who are financially able to own automobiles of any type is comparatively small. This applies to native houses. Many of the transportation lines are owned by Europeans, and these are influenced somewhat by national prejudice, although it has been possible to overcome this in a large measure with respect to pleasure cars during the past year.

Japan, China and Philippines.

In Japan, financial conditions are such at present as to make it a little more difficult to interest the peo-

A cablegram resulted in the shipment of parts another and an older model, which could not be applied to the car in question. The purchaser never was able to use his machine, and over \$8500 was expended for nothing.

It might be contended that this was an isolated case, but exporters assert that they are continually bringing similar stories, making it exceedingly difficult for interested parties in certain localities. Of course, only good American cars and trucks have been shipped to South America during the past two years, and these are giving excellent satisfaction. Germany, France and Great Britain are serious contenders for business, and Americans must expect keen competition. The long delay in securing spare parts makes it impossible to establish service depots wherever practicable.

Present Market Conditions.

Perhaps the best South American market is to be found in Argentina, for it is in this republic, and in Brazil, that by far the larger number of commercial vehicles is owned. Road conditions in Argentina have been improved to a larger extent than in practically any other South American republic, and this work is being carried on rapidly in several sections. Just at present the country is undergoing a financial depression, and it is stated that several hundred thousand dollars worth of cars are being held in storerooms and warehouses, there being no demand for them. This is, of course, a temporary condition, which undoubtedly will be overcome in due time.

Road conditions, outside the larger cities and towns in Brazil, are by no means as good as in Argentina, and this road work is not being prosecuted as energetically. The market seems to be fairly good. The same situation applies in Uruguay. Much road work is under way in other South American countries, particularly in Venezuela, which has proved to be a very good market for American cars and trucks. The demand for automobiles of any type is still limited in some of the other countries, but the work now being done by American manufacturers, their representatives and the exporting houses, is believed to be such that when it is possible to do business on a larger scale the United States will get its full share.

Africa and Australia.

Africa is rightfully considered a new country. Americans are free to compete here on equal terms with all other countries. In many instances American manufacturers have been able to place orders in advance of any other maker. This is particularly true of British South Africa. The motor trucks sold on that continent have given excellent satisfaction, and there seems to be no reason why other sales should not follow. Road conditions are improving rapidly, and the market undoubtedly will keep pace.

Australia, Tasmania and New Zealand are in the same position, the people being very favorably disposed toward American products. The road conditions generally are ideal. These islands are so far from the

country of origin in any event that Americans are not handicapped in this respect. It is possible to secure reliable agents in both Australia and Africa. The other islands of the Pacific offer their own problems.

EXPORTATION OF AMERICAN AUTOMOBILES FOR FISCAL YEAR ENDING JUNE 30, 1913.

Selecting Shipping Route.

Exporters to the Philippines and Asia are compelled to consider the advisability of shipping by way of the Atlantic or Pacific ports. Time is saved by the latter route, but the expense is greater. This is due to the overland freight charges. Shipments from New York, for instance, to Manila by way of the Suez canal occupy from 55 to 60 days, while they will go by way of the Pacific in 40 to 45. It is probable that the opening of the Panama canal will have a decided effect with respect to all shipments going to the Orient.

New Tariff and Imports.

By far the largest proportion of machines imported into this country are handled by importers in New York City. Among these Emanuel Lascaris is regarded by importers and dealers in American cars in that city as best informed respecting the market for foreign cars and trucks. He maintains that the reduction of the tariff on chassis, from 45 to 30 per cent., will have little effect upon this phase of the situation. In addition, he holds that American manufacturers will

REVIEWED CONVENTION PAPERS.

The December meeting of the Electric Vehicle Association of America was held the evening of the 16th, when the members were the guests of the United Electric Light & Power Company at its new auditorium at 654 West 187th street, New York City. Prior to the meeting the members had opportunity to inspect the sub-station building of the company, which is one of the most modern of its kind. The greater part of the evening was given over to reviewing the papers presented at the Chicago convention of the association, these being discussed from varying viewpoints and to considerable length. Following the discussion a collation was served.

MUST PAY FULL DUTY.

A chassis of a motor vehicle built in this country and fitted with a body made abroad, when brought to this country from a foreign nation, may be taxed an import duty of 45 per cent. and the ad valorem required under the tariff law of 1909, according to the determination of the board of United States general appraisers in the case of the General Motors Export Company. This concern imports vehicles of American and foreign manufacture, and maintained that the chassis, being made in this country, and being returned unimproved, was not subject to duty, but the body only was to be taxed on the basis of 45 per cent. The board rejected this claim and stated that as the company had not complied with the customs regulations concerning American productions returned to this country, full duty must be paid. The decision is of decided importance to all manufacturers.

be compelled to adopt new methods of doing business, eliminating the practise of making liberal guarantees. This, he says, is due to the fact that no manufacturer can guarantee his product in the hands of drivers who either do not know or will not take the time to learn how to handle a car. He believes that it is because makers of imported trucks will not permit such liberal treatment that the number of foreign trucks in the hands of users in this country is so limited.

It is of interest, in this connection, to study the latest monthly report of the Department of Commerce covering the importation of cars since the new tariff went into effect. Previous to Oct. 1 the average monthly importation for 1913 was 43 cars, pleasure and commercial, valued at \$100,977. During October there were imported 29 cars, valued at \$75,646. It undoubtedly is too early to judge of the business that will be done in imported machines as a result of the tariff reduction, but the figures for the first month under the new law are none the less interesting.

The Kleiber Company has been organized at San Francisco, Cal., to manufacture service wagons. Paul Kleiber is president, W. M. Remensperger and Edward Kleiber vice presidents, P. F. Rathjens treasurer and O. T. Suden secretary. A machine is now being designed and it is proposed to build it in several sizes. The officials of the company maintain that 100 machines will be produced the coming year, and that these will be marketed on the Pacific Coast.

The advertising department of the General Motors Truck Company, Pontiac, Mich., is now in charge of John E. Baird, who was advertising manager of the Kingman Plow Company, Peoria, Ill., and previously editor of the Implement Trade Journal at Kansas City, Mo. Mr. Baird will also be identified with the sales department to a certain extent.

ADAMS MODEL T TRUCK.

Quickly Convertible Body Equipment Adapts the Machine for Many Purposes.

The model F truck chassis, built by the Adams Motor Company, Findlay, O., which is one of the most important productions offered in the market by that concern, was designed to meet the requirements of those who have work differing widely in character, and not sufficient volume to justify the purchase of several machines having permanent body equipment. The chassis is of two tons capacity and it is practically the same as the model E, aside from the wheelbase and length of some of the components. In every other respect it is the same in design and has all the features that make the Adams machines distinctive. The wheelbase is 115 inches, this making for convenience of operation in traffic and where the conditions are congested or limited, and there is no loss in capacity because of the shortening of the machine.

The chassis is built to endure hard service, and the frame is built of a special high grade of steel, the channel section being pressed to shape. The members are liberal in size and are reinforced and well braced with gusset plates. The frame is mounted on heavy semi-elliptic springs and the axles are of large proportions. The wheels are 36 inches diameter and are shod with solid demountable tires, four inches width single forward and 3.5 inches width dual rear.

The motor is a four-cylinder, water-cooled type, rated at 30 horsepower, that is mounted forward of the dash under a hood of the French type, and the radiator combined with the dash, this affording protection to the cooling system and accessibility of the engine for examination or work.

The body equipment consists of a regular platform loaded with stakes and sideboards, that is removable from the seat back, having a loading space of 87 inches length and 54 inches width regularly, but this can be made to any dimension up to 100 inches width and 96 inches length, these being the maximums recommended by the builder.

With the removing of this body, which can be accomplished very quickly, the chassis can be equipped with a steel dumping body, hot riveted and amply reinforced, that has inclined sides and bottom. This body will contain one, gravel, sand, etc., or 10 cubic yards of crushed stone or tons of coal. The body is mounted on the chassis and is discharged by a trap in the bottom, the load dropping by gravity almost instantly be-

neath the rear end of the body. The body may be loaded by gravity wherever this is possible, and the discharging is controlled by the driver by two hand levers at the left side. The truck can be driven wherever desired and the load discharged, the discharging chute closed and the machine started in about a minute. The control of the body is extremely simple and there is no possibility of failure or breakage, and it will operate positively. In working the truck the driver need not leave his seat. The truck is furnished with the two types of bodies, making it a very useful vehicle for builders, contractors and others who haul differing materials. With both bodies the machine can be utilized for practically all work.

The Stewart-Warner Speedometer Corporation has established additional branches at Atlanta, Ga.; Cincinnati, O.; Kansas City, Mo.; Los Angeles, Cal.; Minneapolis, Minn.; Philadelphia, Penn.; Pittsburgh, Penn.; Portland, Ore., and St. Louis, Mo., this making a total of 17 thus far opened.

Because of the demands for increased production, the Rowe Motor Truck Company, Coatesville, Penn., has acquired factory property at Downingtown, Penn., and the business will be carried on at that place in the future.

Dr. D. B. Bundy of Cincinnati, O., has been named as assignee of the Crescent Motor Truck Company, Middletown, O., which has become financially involved. The assets are stated to be \$2200 and the liabilities are considerably in excess of that amount.

The Northwestern is the name of a 2000-pound delivery wagon that is being built by the Star Carriage Company at Seattle, Wash., the machine being the design of August Greyerbehl and J. G. Eyler, who are the principal owners of the concern.

ADVERTISING RATES.

Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.

Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.

Entered as second class matter, February 25, 1911, at the Post-office at Pawtucket, R. I., under the Act of March 3rd, 1879.

PROSPECTS FOR THE INDUSTRY.

Because there is a general disposition by business men to economize is no reason to believe that industry or commerce will stagnate. Good judgment demands that economy shall be obtained, no matter what the prevailing conditions, although this is frequently defined as efficiency, and means the promotion of production or the stimulation of endeavor to bring about greater returns at the same expense, or the same results at a lessened cost.

One of the largest financial burdens borne by the people is the cost of transportation, and any material reduction in this will be a distinct saving, because there is nothing constructive resultant from it, and it may be likened to a rental paid for a property in this respect. The education of the people to the possibilities of the use of the highways, instead of paying the prices exacted by companies operating transporting enterprises, will, no doubt, result in a very much larger utilization of motor vehicles for business purposes.

The industry is in its infancy. That there will be great development in design, construction and use there is no doubt. Those who desire economy can only obtain it through the study of the subject, and with reference to highway haulage the motor vehicle industry and the trade will profit just so far as endeavor is made to teach the public the possibilities of motorized vehicle equipment. The business man who wants to use motor trucks and wagons must be practically educated to what can be accomplished with them, and not

left to his own resources after he has purchased machines. The example of other industries could be consistently followed in the event of absence of originality, but the concern that is far-sighted enough to have transportation experts, whose service will be available to its customers, will find a very general appreciation of its policy that will be substantially rewarded.

LONG DISTANCE ROAD HAULAGE.

The highways are practically open to the public for the haulage of freight. The limitation of animals for transportation is well enough known, but the possibilities with motor vehicles are little understood. Those who have engaged in freightage in competition with steam and electric railroads have met with widely varying conditions, and have been compelled to work out their own problems. One of the most frequent mistakes is the continuance of methods that were the vogue with horse vehicles, and when this fault is combined with neglect of the machines the results with motorized equipment have not been satisfactory. The purchase of a motor vehicle means the acquisition of a property that can do a stated work, but its productiveness depends entirely upon the owner. Long distance haulage promises much, because in such work the proportion of idle time is less than in short hauls, and business men will consistently support what will create competition with railroads and express companies and directly benefit them.

UNIFORM HIGHWAY LAWS.

States that have highway systems usually have standards of construction, and generally these differ. Supervision, maintenance and repair are often left to the judgment of men who are selected more for their political influence than their knowledge of engineering, and construction is frequently as cheap as the supervising engineers will pass for the contractors. Administrations and methods are frequently changed and new policies are adopted. The same condition obtains with towns and cities. The result is that highways and streets are poorly built and neglected and yet at enormous cost.

While it is true that available materials will differ and the expense cannot always be uniform, there is no reason why standards cannot be adopted for building and maintenance, and the same supervision insured throughout all cities, towns and states. The statement is made that engineers are not agreed as to material specifications or methods, but this will be found true in every phase of engineering, so that this is not an argument why there should not be endeavor made to establish standardization in road making. The impossibility of reconstructing what has already been built is evident, but new work can be standardized and reconstruction can be made to conform to recognized specifications.

SAVE COST IN NINE MONTHS.

Great Economy in Lamp Bulb Haulage by Truck and Trailer Equipment.

The National Lamp division of the General Electric Company, by the use of a special Peerless truck trailer equipment has realized an economy in the age of electric lamp bulbs that equals the investment in nine months, and this principally from saving labor and lessened breakage. The company has a factory at Niles, O., and the bulbs used for manufacturing incandescent lamps are produced there. It is necessary to deliver the bulbs at the lamp factories at Westinghouse and Warren, that state, and the plants can only be kept in operation by continuous delivery of bulbs.

Formerly the bulbs were sent by freight, and to minimize breakage it was necessary to pack each bulb, wrapping it in tissue paper and placing it in a tray. The labor of packing was considerable and despite the best care many were broken in transit. The bulbs are very light, but bulky, and a carload was based on bulk and not on weight. The company decided to use highway haulage. A special Peerless chassis, wheelbase of 204 inches, was bought and on this a body was installed, this having inside dimensions of 17 feet eight inches length, seven feet width and eight feet four inches height. This body has out-sliding side doors, so the full capacity may be used.

The weight of a load for this body, which will hold 100 cubic feet, is less than a ton, and to utilize the power of the machine a trailer was built, this having a frame of channel angle iron mounted on springs and rear and front axles, the wheels being of standard size and shod with solid tires. The trailer is controlled by a drawbar or pole that has a short arm or bracket that is linked to the chassis frame, with a longer arm pivoted on the front axle and which is connected with the centre of the tiebar that extends across the rear of the tail levers on the front axle pivots. Turning the handle from one side to the other swings the wheels and the trailer, while chains are attached parallel the drawbar during straight pull ahead pre-strain that will bend the handle and cause the trailer to follow the track of the truck. On the trailer is installed a body the same size as on the truck. The truck and trailer bodies have a combined capacity equal to the average box freight

macadam and brick paving, with surfacings that are poor for the first two and good for the last. The average mileage daily is 35, and the load will range from 3000 to 4000 pounds for the truck and trailer. The actual cost of haulage is very close to that for rail shipments in carloads, but there is the saving of labor in packing and unpacking, and the breakage is less than half when the bulbs were carefully packed and shipped by rail.

STATE TO USE MOTOR TRUCKS.

If the plans proposed by the New York highway commission are realized the state will purchase a number of motor trucks for use by that department, these to be utilized in maintenance and construction work. Trucks have been used with success by contractors and these types will be purchased and fitted with dumping bodies, tank apparatus and equipment necessary or desirable. With the increase of mileage of improved highways the maintenance work has greatly increased, and the desire of the department is to have such facilities as will make its endeavors in every way practical.

WILL BUILD TRACTORS.

The Mercury Manufacturing Company, Chicago, Ill., has built for a disposal works a tractor having three wheels, the single forward wheel being used for steering and the traction being afforded by the two driven rear wheels. The machine is intended for road work with trains of trailers of ton capacity, the number of units depending upon conditions. The frame of the machine is short and at the rear the chassis resembles the conventional truck. The forward wheel is mounted in what is termed a fifth wheel, it being turned on a table to any angle desired. The motor power is furnished by a 40 horsepower motor and the drive is by jackshaft and side chains. The tractor, with the driver, weighs approximately 6000 pounds.

Peerless Truck and Trailer Used by the General Electric Company for Freighting Between Its Niles, O., Glass Plant and Its Lamp Factories.

roads between Niles and Westinghouse are dirt, worn

ELECTRIC VEHICLES IN CANADIAN CITIES.

SNOW is believed by many to be the greatest obstacle to highway vehicle traffic, and snow falls are apprehended with a considerable degree of uncertainty when a stated work is expected of either animals or motors. It is well enough known, however, that in those sections of the country where snow is frequent and accumulates to considerable depth during winter, the steam and electric railroads have no more difficulty in operating than in other localities where the heaviest winter storm may bring five or six inches.

It is the custom to associate the climate of Manitoba with very low temperatures and heavy storms, and a belief very generally prevailing is that road haulage is very difficult a great deal of the winter months. But as a matter of fact the continued cold weather and the absence of the constant thaws of lower latitudes afford substantial roadways, the worst experience being in the spring when the snow and ice melt and the ground is water saturated.

That more than 40 electric wagons and trucks are

direct from the manufacturer. In contrast with this condition the statement may be made that there are from 15 to 20 agencies representing the best known gasoline wagons and trucks.

Winter Weather in Toronto.

To understand the winter conditions in Toronto a comparison may be made of the snow fall in that city and in Detroit and Chicago for two years, which will probably be accepted as representative. During the winter of 1910-11 the precipitation of snow was as follows: Chicago, 29.6 inches; Detroit, 50.2 inches; Toronto, 61.3 inches. Winter of 1911-12, Chicago, 39.6 inches; Detroit, 58 inches; Toronto, 76.4 inches.

The experience of users of electric vehicles in Toronto has been that mere low temperature has no appreciable effect whatever on electric truck efficiency, and that there is not the loss of mileage capacity that is resultant from use in mud or sand, the latter condition being quite as much realized with gasoline machines as with electrics. In fact, the rainy and muddy periods of the spring and autumn are the greatest de-

The Fleet of Five Detroit Electric Wagons in the Service of the Robert Simpson Company's Department Store, Toronto, Ont.

in use in Winnipeg may be a surprise to those who believe the highways in that locality are obstructed half the year, and an awakening of those who believe that the winter weather, such as is usually experienced in New York, Boston, Philadelphia, Buffalo, Detroit, Chicago, Milwaukee and other cities in the northern half of the United States, would militate against the efficient operation of electrically driven machines.

As a matter of fact the electric vehicles used in low temperatures have been found in every way dependable, and that doubt exists is due largely to the lack of accurate knowledge of results. Information of the operation of electric vehicles is not general and supposition has led to opinions that have no foundation in fact. This is especially demonstrated in Toronto, where the snow fall is exceedingly heavy, by the use of 32 electric wagons and trucks, some of which have been used for years with very satisfactory service at all times. Up to the summer of 1912 there was not an electric vehicle agency in Toronto, and, in fact, all the electric service wagons ever sold in that city have been either bought through the one pioneer agent, or

terrents to a wider use of motor vehicles in Toronto. In the suburbs are many unpaved streets where new building operations, new stores and new residences must be reached, and these are softened and badly cut by the vehicles used in them. The more the traffic the greater are the difficulties met with and the corresponding loss of time. During the last three years the electric wagons used in Toronto have never been withdrawn from work save such short period after severe blizzards that necessitated at least a partial cessation of all horse and motor haulage.

Electric Users in Toronto.

The oldest user of electric vehicles in Toronto is the Verral Company, which conducts a public service, operating nine sight-seeing machines and a taxicab. The fleet consists of a 20-passenger Riker wagonette 10 years old, three Commercial 38-passenger wagons seven years old, five Motor Car Equipment Company's 38-passenger wagons six years old, and a General Vehicle taxicab more than seven years old. Of these the material for the Commercial machines was bought and the vehicles were assembled in Toronto. The sight-

g electrics are used during the spring, summer and autumn, making regular trips about the city, and during that period as many miles as many horses in regular service make during a year. Despite the machines are comparatively old they are giving entire satisfaction despite the hard work required of them. The taxicab is driven the entire year, and the idea of the work done can be gained from the fact that since June 1, 1913, it has been run more than 100 miles.

The other users of electric service machines in Toronto are: Robert Simpson Company, department store, five Detroit wagons; Heintzman & Co., piano manufacturer, one Detroit wagon; Murray-Kay Company, furniture, one Detroit wagon; M. Langmuir Manufacturing Company, trunk manufacturer, one Detroit wagon; Holt-Renfrew Company, furrier, one Detroit wagon; T. R. Estabrooks Company, tea importer, one Detroit wagon; Bowles Lunch, Ltd., restaurateur, one Detroit wagon; McClary Manufacturing Company, stove manufacturer, one Detroit wagon; O'Keefe Brewing Company, brewer, four General Vehicle trucks; Canadian Express Company, three General Vehicle wagons; Toronto Electric Light Company, one General Vehicle and one Waverley wagon; Central Press Agency, Ltd., one Waverley wagon.

The O'Keefe Brewing Company was the pioneer user of electric trucks in Toronto, having used two trucks through three winters, and two others that were bought the following year. The test of the winter of 1910-11 was the reason for the purchase of the third pair. The Holt-Renfrew Company used a machine at Winnipeg during the winter of 1911-12 before the wagon now at Toronto was purchased, and the latter vehicle is now working in its second year. The machines of the Canadian Express Company, Heintzman & Co., and the Langmuir Manufacturing Company have all been worked through one winter at least, and the results obtaining with continued operation of the first wagon prompted the purchase of four additional wagons by the Robert Simpson Company. The Simpson Company uses its machines for general purposes, including parcel delivery, furniture haulage, warehouse transfer work, and with entire satisfaction to the concern and its customers.

The experience of the firms that have been stated has been practically the same so far as efficiency is concerned, although service requirements vary materially, and continued use has demonstrated that electrics are in every way dependable and reliable. With improved road surfacing the economy would be even greater, but this result would obtain whatever type of vehicle was used, either electric, line or animal drawn.

MAMMOTH GOODYEAR PLANT.

Factories Have Floor Space of 35 Acres and Employ More Than 6500 Hands.

The factory plant of the Goodyear Tire & Rubber Company at Akron, O., which has been developed within a very few years, is one of the largest and most modern rubber manufactories in the world, it being an example of the almost marvelous increase of the motor vehicle tire industry. The plant is located on a tract of 50 acres, this large area being acquired to provide for expansion and to insure railroad and other facilities essential to economical and satisfactory operation.

The buildings are of the most substantial and approved construction, having a floor space of 1,500,000 square feet, or approximately 35 acres, and in these about 6500 people are employed. The power plant is very large, having steam boiler capacity of 12,000 horsepower, turbo-generator capacity of 8500 horsepower, and a steam engine capacity of 7250 horsepower. The plant is equipped throughout with machines and tools of large capacity and modern construction, the purpose being to insure high class production in great quantities. The plant can produce 10,000 pleasure car tires daily, in addition to the immense output of motor truck, motorcycle, bicycle and carriage tires. The mechanical rubber goods department, which was established less than a year ago, is constantly increasing its production, including belting, hose, packing, etc., which is fast becoming recognized by the trade as equal in quality to other Goodyear products.

The Lloyd Auto Delivery Company has inaugurated business at Jackson, Mich., and has in service six Commerce delivery wagons that are driven a daily average of 35 miles, the routes being over all kinds of paved and unpaved city streets and country roads. The company has contract for the delivery of a number of stores of Jackson, and adopted the Commerce machines after careful inquiry into the merits of a number of vehicles of the size required.

Factory of the Goodyear Tire & Rubber Company, Akron, O., on a Site of 50 Acres, Having 1,500,000 Square Feet of Floor Space and Employing 6500 Persons.

PRACTICAL PURPOSE TRUCK.

Wichita Two-Ton Machine Designed for Endurance Under Severe Conditions.

The model B truck chassis built by the Wichita Falls Motor Company, Wichita Falls, Tex., is constructed to a design developed for all the vehicles produced by this concern, and differs from the model A machine merely in frame and other proportions, the power plant being the same. The chassis is designed for long endurance under severe operating conditions and with a wheelbase that will make it a convenient machine in congested traffic and where the space is limited. The components are heavy and of material that will insure hard service, and the construction is simplified to afford accessibility and to economize labor in attention and maintenance care.

The power plant is especially well developed, the motor being a four-cylinder, water-cooled, L head type, cast en bloc and so built that work on it may be done with a minimum of labor, dismantling not being necessary even for an overhaul. The cylinders have bore of 3.25 inches and stroke of five inches, this giving a horsepower rating of 16.7 by the S. A. E. formula, but the claim is made by the maker that with the bore to stroke ratio of 1:1.65 at least 25 brake horsepower is developed. The crankcase is a barrel type with large bolted-on plates carrying the end main bearings, and with a base that forms the oil reservoir. By removal of the base and the end plates, and after loosening the connecting rod big ends, the crankshaft may be drawn out without difficulty. The timing gears are forward of the front end plate and are housed in a case that is separate from the crankcase and has independent means of lubrication.

The valves are at the left side of the motor and the mechanism is not enclosed. The crankshaft is very large and is carried on extra long main bearings provided with case hardened sleeves, pressed into position and ground to a fine finish. The bearings are a special nickel bearing metal. Great care is taken to finish

the cylinders and pistons. The valves are provided with cover plates that afford convenient access to the valve pockets and cylinders, so that carbon may be easily removed. The valves have cast iron heads electrically welded to nickel steel stems. The valves are operated by a one-piece camshaft, that drives the oil pump, and the magneto is driven by a gear that meshes with the camshaft gear. The magneto is located on a bracket mounted on the left side of the crankcase, where it is protected by the frame of the chassis.

The motor is cooled by thermo-syphon circulation of water through large cylinder jackets, ample manifolds and a radiator carried on trunnions at the front end of the chassis, radiation being insured by a six-bladed fan mounted on a shaft in a ball bearing bracket, driven by an adjustable belt from a pulley on an extension of the crankshaft. The engine is lubricated by a combined splash and mechanical force feed system, the oil circulating through a glass indicating gauge installed on the dash. The ignition is by either Bosch or Eisemann magneto, and the carburetor is an automatic float feed type.

The clutch is a leather faced cone of ample proportions and the power is transmitted by shaft through a gearset of a sliding gear selective type having three forward speed ratios and reverse, and thence to a jackshaft and side chains to the rear wheels. The frame is a pressed steel channel construction, carried on semi-elliptic springs, the rear suspension being with outside brackets. The front axle is an I section and the rear axle a rectangular section, both drop forged from high grade steel. The chassis is right side drive by a worm and worm wheel system, with centre speed changing and emergency brake levers, and with the ignition and fuel control levers mounted on the steering column. The service brake is operated by a pedal, having shoes expanding in drums on the jackshaft, and the emergency brake shoes expand within drums on the rear wheels. The wheelbase is 118 inches and the tread 56 inches. The wheels are 34 inches diameter, having 3.5-inch shoes forward and three-inch dual tires rear, and are fitted with demountable rims. The gasoline capacity is 24 gallons.

The chassis are fitted with varying body equipment suited for any service, and are also equipped with fire department apparatus. The Wichita machines are extremely well known in the Southwest, where a considerable number are in use, but the company has not as yet made a campaign in the East, though it is extending its agencies into the Southern states and the Middle West. The factory facilities are excellent, and the company will later increase its plant.

Model B Wichita Truck, Capacity 4000 Pounds, 144 Inches Wheelbase, Built by the Wichita Falls Motor Company, Wichita Falls, Tex.

ELECTRIC VEHICLE PRACTISE.

Cell Capacity Proportioned by the Size of the Element and the Construction and Character of the Plates--The Effect of the Electrolyte upon the Electrodes and the Relative Endurance of Positives and Negatives.

William W. Scott.

WHILE a cell will have a voltage that is governed by the potential of the electrodes, which fact has been sufficiently explained, the capacity, which is measured in ampere-hours, will increase or decrease as the cell varies in size. Ampere-hour capacity is accepted as the number of hours that one ampere will be delivered. As cells are now made practically on the universal standard of eight-hour charge or discharge, a cell that is rated at 200 amperes, for instance, will deliver 25 amperes for eight hours, and as the discharge rate is increased the capacity will diminish until when discharged in one hour about 100 amperes could be a normal output. This ratio will vary slightly with the form of plates, there being the least loss with

Plante or formed type, and the most with the pure or pasted plate. The output of energy is expressed in watt-hours by multiplying the ampere-hour put by the average voltage of the discharge.

Cell capacity is dependent upon the character, porosity and disposition of the active materials composing the plates, the volume and density of the electrolyte, the character of diffusion, the temperature and the discharge rate. It is understood that with a Plante type the active material is formed on the surface of a sheet of lead, or composition of which lead is the chief element, and the surface is increased by shaping the plate, generally by grooving or corrugations. Plante plates never have the degree of porosity reached with the pure plates and the latter as a rule are more permeable, so that the more complete the saturation of the active material the greater the discharge capacity of the cell. The volume and density of the electrolyte are, of course, material factors. The temperature has not been considered, and the rate of discharge is variable, according to the requirements of the user.

The discharge of the cell from the maximum of charging, 2.55 volts for instance, to a minimum of 1.80 volts, will yield the amperage capacity, these extremes being accepted as standards by battery engineers and manufacturers. To discharge the cell below the minimum would result in excessive sulphation and damage from expansion, distorting the frames and loosening the active material without any useful purpose being served. These standards can be accepted for any rate of charge or discharge.

The best results from cells can be obtained when complete charging and discharging can be accomplished, and the cycles of operation are regularly repeated. In addition to this the cells should be charged as quickly as is possible after being discharged. If a

battery is to be idle for a short period it should be charged to approximately the maximum.

To illustrate the variable character of cell capacity the statement can be made that the ampere-hour output will vary from 40 to 60 a square foot of area of surface of Plante type plates, and from 50 to 75 for plates of the Faure form, the value of the former being dependent upon the depth of the formation of lead peroxide and the construction, and of the latter upon the porosity and thickness of the plates.

Now as to the effect of the electrolyte upon the plates. The lead peroxide coating or film on the positive plate is permeable and it will absorb a considerable volume of electrolyte. The activity of the plate is proportionate to the surface that actually contacts with the solution. The formation of lead sulphate with the discharge is within the pores of the peroxide, as well as on the surface, and as these crystals are not

Example of the Lessening of Cell Internal Resistance Following a Discharge.

completely reduced by the charging, the accumulations force minute particles of the peroxide from the plate and also reduce the porosity of the peroxide. When the plates are the Plante type, as the active material is loosened and is precipitated the electrolyte forms new peroxide from the lead that is exposed. If the plates are Faure type the same process follows, but the loss is certain because there is no material from which new peroxide of lead can be formed.

While the positive plates should, in theory, because of the lesser degree of porosity, be larger than the negative plates, owing to the porous nature of the sponge lead, experience has taught the necessity of making the negative plates considerably greater in capacity, as the pores of the sponge lead gradually contract from the effect of the electrolyte and the metal becomes less cellular. There is further reduction by the formation of the crystals of sulphate in the cells. Considerable success has been obtained by incorporating porous

material in the negative plates that will not be affected by the electrolyte, such as coke, porcelain or pumice in pulverized form. Another method is to heat the plates to such an extent that they will absorb a material that can be liquified and which will wholly or partially fill the cells and yet be permeable to the electrolyte, although not soluble in it. This process is known as "permanizing" and it is maintained that by its use lost capacity can be restored to negative plates.

Observations demonstrate that negative plates on which the active material is thin will lose capacity faster than those with thicker formation, and that the loss is in proportion to the number of discharges. They gain capacity for a few cycles and then begin to decrease unless they are treated to permanize them.

The action of the electrolyte upon the positive plates differs from that upon the negative plates. Generally the capacity of Faure plates is increased for a short time and then the disintegration of the active material is begun, the minute particles being loosened and precipitated. With the decrease in porosity the capacity of the plates lessens gradually, and finally reaches a point where the cell can practically discharge

Curves Illustrating the Capacity Loss of Plante Negative Plate and the Result Accomplished by Permanizing.

no energy. The Plante plates will increase in capacity for a brief period, and as the active material is lost this is replaced by new formation until the lead of the plate is exhausted.

The variance of capacity with the change from the standard eight-hour discharge rate can be determined by formula, but there are numerous variables that must be given consideration to insure accurate data. For all practical purposes, however, one may assume that the following figures are reasonably correct:

Discharge Rate	Capacity	Discharge Rate	Capacity	Discharge Rate	Capacity
8 Hours	100	5 Hours	89	2 Hours	65
7	97	4	83	1.5	57.5
6	93.5	3	75	1	50

Besides the lessened capacity there is danger of damaging a battery by quick discharge, and under no circumstances should a battery be discharged more than 20 minutes at the one-hour rate, except in emergencies, where a 20-minute rate may be used for a period not exceeding two minutes. A battery can be discharged at a fast rate for a short time to a voltage below what would be safe at the normal discharge

rate. That is to say, that were the discharge stopped at 1.8 volts a cell there would be considerable residual energy remaining that would be manifested by recuperation within a short time. For this reason a quick discharge may show a voltage of 1.60 without damage to the cell, though under no circumstances should there be discharge below 1.75 when discharging at the eight-hour rate.

The greatest efficiency of a cell can be obtained by discharging at the normal rates, and the greatest capacity for work is evidenced after charging slowly. The charging that is accomplished with the least gassing is not only the most economical as regards current cost, but there is minimum deterioration of the plates. Where the charging is variable the output will also vary. That this may be clearly understood it may be well to instance probable conditions and results, assuming that endeavor is made to operate and maintain the equipment as directed by the builder.

Charging may be taken as the first operation of a cycle of a battery cell, and as cell capacity, and of course service and endurance, is dependent upon the number of complete cycles and not upon the aggregate of ampere-hours output, it is apparent that use should be with the purpose of obtaining as near as is possible the practical completion of the full cycle. If, after the charging, the battery is used, and the discharge is slight, use should be continued without additional charge until at least 50 per cent. discharged, even if the discharging is extended over a period of several days. But when discharged below that point it is well to charge it if the rest is to be for more than a few hours, such as intervals between use during a day. One reason for this is the continuation of the formation of sulphate and the increased difficulty of reducing it by electrolysis, necessitating the use of more current than would be required were discharge immediately followed by charging. Another reason is the loss of a portion of the residual charge by the absorption of hydrogen. But the greatest efficiency is when the charging quickly follows the discharge.

Where the charging and discharging rates are comparatively low the voltage curves more nearly approach each other, the former representing the least consumption of current in energizing and the latter, the greatest value in useful work or efficiency. Rapid discharge increases the polarization and the reduction of the concentrated acid in the cells of the plates causes a quick drop in potential. This explains the retention of what is known as the residual charge and the recuperation of the cells, for there is not as complete diffusion when the discharge rate is rapid. Should a cell be charged slowly and then discharged quickly, the current required for the next charge will not be as large as for the previous energizing, for the residual energy is added to until the voltage reaches the maximum. Another slow discharge will develop more energy than was actually put into the cell, this evidencing the accumulation of the charge.

In charging the decomposition of the water in the

electrolyte and the liberation of the acid radical from lead sulphate creates hydrogen gas that is liberated as the charge progresses, and when a certain age has been reached the gas appears in bubbles on the surface. At this point it is customary to reduce the amperage of the current, for the gas represents a loss of energy, and to continue charging until the voltage remains stationary. If the charging is at high rates the degree of diffusion is low and the high concentration of the acid in the cells of the active material causes voltage to raise rapidly. The condition necessitates a higher charging voltage and the energy in excess of that stored is lost. The quick concentration of the acid is accompanied by heating of the cells, and the heat is higher than the temperature caused by internal resistance. The critical point of a lead-acid cell, so far as temperature is concerned, is 110 degrees Fahrenheit, and heating beyond this is regarded as decidedly deteriorating. Discharging a cell is accompanied by a decrease of temperature because of the boiling of the water as the acid is concentrated in the pores of the plates, there being a specific tendency to draw it from internal resistance, but the former influence is by far the greater.

The life of lead-acid cells depends upon the endurance of the positive plates, and in practical operation these batteries two policies are followed by those using them. The one is to renew the element, both positive and negative plates, and the other is to replace the positive plates after a cell has reached a capacity where it will not afford the mileage and use of new and old negatives as an element. This is known as rebuilding, and while some will maintain it is economical, there are others who believe in complete renewal. Renewing the element will certainly afford maximum capacity, but rebuilding is claimed by many to yield practical results at a decidedly reduced cost.

In connection with this the experience of the New York Edison Company is decidedly of interest. The batteries in use in its machines, which number in excess of 100, are operated after purchase until minimum capacity is reached, and then the cells are rebuilt, the material being procured from the manufacturers and the assembling being done in the battery department of the garage. After reforming charges have been given the cells are assembled as batteries and used. An allowance is made for old material returned to the battery makers, and the work is done in the company's shops, the cost is comparatively small when contrasted with the purchase of new cells. Without attempting the make of batteries, which are regarded as being the equal of any procurable in the market, the following results will show the life of the negative and positive plates as taken from the records, an average being given for the vehicles used in differing work:

Eight surreys, used by officials of the company for the transaction of business in and around the city, averaging from 15 to 50 miles daily on one charge:

No. Cells	No. Plates	Life and Mileage of Batteries Positive		Negative	
		Days	Miles	Days	Miles
11	11	368	9380	650	13,000

Eighteen 2000-pound wagons, used as arc lamp and meter wagons and for the general delivery of material to and from station, etc., averaging 30 to 40 miles daily on one charge:

No. Cells	No. Plates	Life and Mileage of Batteries Positive		Negative	
		Days	Miles	Days	Miles
44	15	390	9000	700	15,000

Two 4000-pound wagons used for general delivery and delivering material to jobs, averaging from 30 to 35 miles daily on one charge:

No. Cells	No. Plates	Life and Mileage of Batteries Positive		Negative	
		Days	Miles	Days	Miles
44	16	300	8130

One 5000-pound wagon, two three-ton trucks and one 3.5-ton truck, used for hanging electric signs and street arc lamps, averaging from 20 to 25 miles daily on one charge:

No. Cells	No. Plates	Life and Mileage of Batteries Positive		Negative	
		Days	Miles	Days	Miles
44	x1-17 x2-19	354	5336	424	7,080

Six five-ton trucks, used for pulling and hauling cable and general heavy trucking, averaging from 18 to 23 miles daily on one charge:

No. Cells	No. Plates	Life and Mileage of Batteries Positive		Negative	
		Days	Miles	Days	Miles
48	x5-23				
44	x1-25	395	4000	729	8,250

*Data not complete.
xFirst figures indicate number of vehicles and second the number of plates.

Chart Showing the Decrease in Capacity of Plates or Formed Negative Plates with Increase of Number of Discharges.

Considering these statements for a moment, it is seen that the vehicles range from the heavier types of pleasure cars to large trucks, and that these were worked from averages of 50 miles for the former to 23 miles for the latter, taking the maximum. Rating the positive plates at a value of 100, in the surrey class the negative has a relative value of 1.3560 by miles and 1.7663 by days' service. In the 2000-pound classification the value of the negative plates is 1.7222 by mileage and 1.7948 by days' service. With the 5000, 6000 and 7000-pound vehicles the value of the negative plates is 1.3266 by mileage and 1.1978 by days' service, and with the 10,000-pound trucks the value is 2.0650 by mileage and 1.8456 by days' service. These figures are especially interesting, as they show the actual values of the plates as demonstrated by careful record and practical experience. There is extreme probability that these would be paralleled in similar service and with equally good supervision and care.

The facts relative to the records of New York Edison Company are given at this juncture for the purpose of illustrating the life of the positive and negative

tive plates, and analysis of the mileage averaged for the plates shows that there are surprisingly close results afforded by each, in some cases the average of the positive slightly exceeding that of the negatives, and in others the negatives affording somewhat more than the positives. Considering the numerous variables the results are surprisingly close and seemingly bear out the supposition of economy that prompts rebuilding of the cells and obtaining the fullest value of the elements.

Note should be made of the fact that the batteries referred to in the record were driven in all kinds of weather and in widely varying operating conditions, and the observations covered a period of two years. The experience was with rebuilt cells in 44 different vehicles and they were found to justify the attention given to them. This is probably the most comprehensive practical trial ever made of rebuilding cells and it can be accepted as representative of the values of both positive and negative plates.

(To Be Continued.)

ENGINE BUILDERS ORGANIZE.

Representatives of automobile engine building firms formed at Cleveland, O., recently the Automobile Engine Manufacturers' Association, the purpose of which is general promotion of trade interests. The firms interested in the association are the Rochester Motor Company, Rochester, N. Y.; Lycoming Foundry & Machine Company, Williamsport, Penn.; Herschell-Spillman Company, North Tonawanda, N. Y.; Clark Motor Company, Jackson, Mich.; Sommer Motor Company, Bucyrus, O.; Waukesha Motor Company, Waukesha, Wis.; Buda Company, Chicago, Ill.; Model Gas Engine Works, Peru, Ind.; Falls Machine Company, Sheboygan Falls, Wis.; Northway Motor Manufacturing Company, Detroit, Mich.; Wisconsin Motor Manufacturing Company, Milwaukee, Wis. The officers elected were: President, Charles B. John of the Wisconsin Motor Manufacturing Company; vice president, A. Knobloch, Northway Motor Manufacturing Company; secretary and treasurer, A. R. Clas, Falls Machine Company.

EQUIPPING NEW G. V. PLANT.

The new factory building of the General Vehicle Company's plant at Long Island City, N. Y., is now being equipped with the machinery and machine tools, and it is probable that this work will be completed so that production will be to the normal standard in a very short time. The building is the largest of the group that will be built, being six stories, 750 feet long and 200 feet wide, and constructed of reinforced concrete. It is practically fireproof and contains every desired facility and convenience. It is one of the largest manufacturing units on Long Island. The first five floors will be used for manufacturing electric wagons and trucks, and the sixth floor will be largely

devoted to the offices of the company. The increased capacity of this division will triple the production of electric vehicles.

The building formerly utilized for the building of electrics will be used for the construction of General Vehicle Mercedes six-ton gasoline trucks, the company having the right to manufacture these machines in America, and these will be produced in such numbers as business conditions warrant. The erection of a large garage and other buildings, which will be used for vehicle building later on, will be completed during the coming year. The district managers and other selling representatives were present when the new building was occupied formally.

S. A. E. RESEARCH COMMITTEE.

According to statements made, it is the purpose of the Society of Automobile Engineers to undertake technical research which will be placed in the hands of a committee made up from members of the faculties of several well known educational institutions, and this committee will co-operate with the society along lines that will appear to be desirable and profitable. The committee will be headed by David L. Gallup, professor of gas engineering at the Worcester, Mass., Polytechnic Institute; and it will also include Prof. E. C. Carpenter of Cornell University, Prof. C. F. Locks of Columbia University and Prof. H. F. Thompson of the Massachusetts Institute of Technology. The committee is to test automobile parts and accessories without bias or partiality, and will make its reports to the society. Many of the tests will be conducted at the laboratory of the Worcester Polytechnic Institute.

The Goodyear Tire & Rubber Company declared a dividend of 12 per cent. on its common stock at its annual meeting. It was stated that the value of the production of the company was increased from about \$26,000,000 to \$33,000,000. The company has during the past year begun the operation of a mechanical department, but the greater part of the business is in vehicle tires.

The Chase Motor Truck Company, Syracuse, N. Y., has for the past few months made endeavor to extend its sales organization, and has since this campaign was inaugurated made 54 agencies, which include representatives in 16 states, and in Germany, Peru and Jamaica, as well as 35 sub-agents for a selling agent at Dallas, Tex.

The Stewart Motor Corporation, Buffalo, N. Y., has made agency contracts with the following concerns: Main Street Garage, Akron, O.; F. E. Avery & Son, Columbus, O.; Andrew Murphy & Son, Omaha, Neb.; Stowell Motor Car Co., Syracuse, N. Y.; H. L. Kearns Auto Company, Portland, Ore.

MOTOR TRUCK SPRING DESIGN.

Excessive Strain from Road Shock While Under Stress of Load Requires Careful Proportioning--Dimensions Approved by Manufacturers with Long Experience.

SUSPENSION of vehicles intended for service involves many factors that are not met with in designs for pleasure cars. That these conditions may be better understood it may be well to differentiate them somewhat. The pleasure car is intended to be driven over smooth surfaces, and with comparatively light loads. The weight upon the forward springs is ever greatly varied, but the load on the rear wheels is generally variable. Moving slowly, the road shocks are minimized, and the deflection and reflection of the springs at the rear compensate these to a considerable degree. But with the increase of speed the movement of the springs becomes greater and more time is required for them to return to what may be termed equilibrium, or a state of rest. The heavier the load the more gradual the movement, and as the speed is usually less with the increase of the load the stresses from road shock are relatively reduced. Driving at a given rate of speed over a given surface the movement of the springs is lessened as the load is increased. The

With the pleasure vehicle the easy movement of the spring is sought, the purpose being to have extreme elasticity, depending upon weight of load or shock absorbing devices to reduce excessive movement, while with the service wagon the spring must be elastic when supporting its load, yet when driven without load the springs are stiff and lack elasticity that is regarded as necessary for protecting the mechanism while loaded. This is a condition that cannot be changed with suspension that is not variable. The springs of a vehicle designed for carrying freight are determined with reference to a maximum weight of load, and when this maximum is placed upon them the springs are expected to have a reasonable margin of safety. The value of this factor is dependent upon the judgment of the spring maker, who determines it from his experience and from known standards of metal strength, elasticity, and from effects resultant from tests according to engineering principles.

When a vehicle is driven over a smooth surface

Fig. 1—Showing the Difference Between the Movements of the Axles and Bodies of Vehicle When the Rear Wheels Contact with Road Obstructions.

spring is not variable. The other factors of use vary decidedly.

The suspension of a service vehicle must have provision for carrying the full load, and assumedly at maximum speed over all kinds of street and road surfaces, and the weight supported will range from 10 to 50 per cent. forward and 70 to 90 per cent. rear, generally speaking. The weight of the load carried has the effect of steadying the movement of the body of the springs, and under severe stresses the compression and recoil of the springs are comparatively slow. With the pleasure car long springs are expected to afford a slow movement, but quick action from severe shock may be compensated to some extent by auxiliary springs and shock absorbers. The springs of the service vehicle must be proportionately shorter to sustain the load, and yet have sufficient elasticity to minimize the vibratory effects upon the body and mechanism they support.

the wheel is assumed to have continuous contact with the plane on which it moves, but when any obstacle is met the effect is dependent upon the speed. When starting, if there be a condition that will have the effect of "chocking", the power must lift the weight upon the wheel over the obstruction, and obviously the force must be greater than when moving, for the momentum of the vehicle will contribute materially to the lifting. Starting from idleness the power must actually lift the weight, whatever it may be, and there must be sufficient traction to afford this result.

Considering the front wheels of a vehicle that is driven by power applied at the rear wheels, it will be understood that these are lifted entirely by the momentum, and being free to revolve in either direction the effect when contacting with an obstacle is to stop them, and then they are carried upward by the forward movement. The rolling tendency of the forward wheels is not changed with variations of speed, but

there is a deflection of the springs proportionate to the force of propulsion.

The rear wheels, however, are driven by power, and in theory, at least, these are moving at a stated number of revolutions. When starting there is the necessity of lifting the weight upon these wheels over an obstruction before them, and this must be accomplished by power applied. After starting there is the power of the motor and the momentum in combination. The forward wheels are "pushed" and there is not the resistance to be overcome that is met with by the rear wheels, because with these traction is absolutely necessary to movement, and unless this traction is positive the gravity influence of the weight tends to stop the vehicle. This condition may be observed when a motor vehicle is driven on any surface where traction is not certain, and the wheels revolve without imparting power.

Observation of a "pushed" wheel will show that it will lift more easily over a road obstruction than a traction wheel, for the latter will strike an obstacle

sufficient, the tire leaving the plane of movement a number of times, each upward movement decreasing materially in height. The movement of the axle is taken by the spring and the rise and fall of the frame, body and load (which are to be regarded as a unit) is much slower. This difference between axle and frame motion, illustrating the influence of the spring, is shown at Fig. 1, which gives the results of experiments made by G. H. Baillie, a member of the British Institution of Automobile Engineers, and represents the movement of a vehicle over a curved obstacle that insured very gradual lifting and lowering of the wheel. The sketch at A shows the effect, which might be expected with a machine of ordinary proportions, when lifted above an obstruction two inches high. From this it will be noted that the wheel moves very quickly upward, and that the frame and body lift slowly in comparison. The sketch at B shows the movement of the wheel and body at double the speed as in A, with retardation of the spring movement by friction, so that the rise of the body was more gradual and the fall was

Fig. 2—Illustrating the "Bounding" Movement of a Wheel After Passing Over an Obstacle or an Inequality Existing in the Surface of the Road.

and the combined force of traction and momentum will cause it to "jump", (which word will serve in the absence of a more specific definition) and this will cause a more violent upward movement of the axle, and, of course, reflection that will be proportionate to the deflection of the springs. The movement of the axle has a tendency to compress the spring against the weight it carries, and the frame, body and load are carried upward to a point dependent upon the elasticity or shock absorbing quality of the spring.

The movement of the wheel is somewhat influenced by the resiliency of the tire between it and the road surface, and the shock absorption is dependent upon the type of the shoe, so that the shock imparted to the wheel is not as violent as that sustained by the tire. The tractive effort is continued by the wheel in surmounting the obstacle, and this and the momentum cause the "jump", which carries the wheel usually higher than the obstruction and forward through space until gravity and the reflection of the spring bring the wheel in contact with the surface. There is, however, a bounding effect if the speed be

extended over a longer period. The result was an easier motion of the vehicle.

These two sketches show what may be regarded as the general effect of road shock with and without absorption, although one must understand that this is not representative of the value of any particular device. Neither is there representation of any condition that may be regarded as standard.

In Fig. 2 are shown sketches intended to illustrate the effect of the "jump" of traction wheels caused by obstruction in the path of the wheel or inequality in the surface of the roadway. These differ from those denoted in Fig. 1 in that they are intended to show the movement of the wheels with relation to the plane on which they move, and the "bounding" caused by the resiliency of the tires and the elasticity of the springs. A illustrates the effect of an obstacle on a smooth surface and B shows the result of inequalities in a roadway, in both instances the "bounding" being exaggerated to clearly present the vertical movement.

Any increase of speed necessarily adds to the rise and fall of the axle and proportionately affects the

body and load, and the effect is to deflect the spring until it will lift the frame and the weight it carries, the deflection causing the rise of the axle, and the reaction causing the rise of the body. The initial "ump" is followed by the bounding until the wheel comes to a rest.

Now it is evident that the deflection of a spring is resultant from pressure that straightens the leaves from the ends toward the centre, and as the lengthening from the deflection is not resisted by shackles the greatest movement of the spring is noticeable where the pressure is applied. This is illustrated at Fig. 3, the examples being semi-elliptic types of different length. Obviously the shorter spring as shown at A will be stiffer, and the deflections and reflections will follow each other in more rapid succession than with the longer, as seen at B, it being assumed that conditions other than spring length are alike. The shorter spring is decidedly less sensitive and that protection afforded to the frame and body is not as satisfactory.

But in practice it must be understood that there are three different conditions to be considered, all of

The minimum arc of springs off the axle is three inches and the maximum is seven inches, this variance

Fig. 2.—Demonstrating the Variance in Deflection and Reflection of Short and Long Springs as Used for Vehicle Suspension.

which are variable, the load, the speed and the road surface. The spring, which must be constant, is expected to have sufficient elasticity to absorb all shocks under all loads, from minimum to maximum. Obviously the spring cannot be uniformly efficient with every condition, and if it is elastic when carrying the maximum load it will necessarily be stiff and slow when but partially loaded. This is practically the condition with motor vehicles that are built to carry weights of several tons. While these will ride easily with a full freight they are so suspended that when given light the vibration is extreme, and for this reason the statement is justly made that greater wear is caused from use unloaded than when used loaded.

In the following statements semi-elliptic springs only are considered, and the sizes of vehicles are those in general service. There are no standards recognized by vehicle builders, but the Perfection Spring Company regards the dimensions stated as fairly good practice:

1000-Pound Wagons.			
	Width In.	Length In.	No. Leaves
Front	2	40	8
Rear	2	46	8-9

depending upon the spring and its use. The supposition is that the maximum arc will apply to the springs of large dimensions. It will be noted that this tabulation gives a difference of 25 per cent. between minimum and maximum length and there is a difference of 75 per cent. in width, the strength being supplied by additional leaves. In the five-ton truck springs the greatest width and fewest number of leaves have been found in the construction of the White machines. This has not, however, been adopted generally.

One of the most interesting facts developed in vehicle spring engineering is that the factor of safety usually allowed is 100 per cent., but the percentage of overload that can be regarded as safe is approximately 30, which can be estimated by the owner or user of any machine. Those who sanction overloading of vehicles can understand that there is a certainty of crystallization and permanent sag developed from the excessive strain upon the fibres of the steel. There is no point where this danger can be anticipated because crystallization may result earlier or later with differing qualities of metals, and sag may be caused by a

single overload, although it is more often resultant from standing with loads, as in a garage when loading is done over night without jacking the body to lessen the static strain. Fatigue is very quickly developed in a front spring and overloading might cause breakage at the centre bolt.

From another source the statement is obtained that the length of front springs for power wagons and trucks should range from 38 to 48 inches and the widths from two to three inches, and the rear springs should be from 48 to 54 inches length and from two to four inches width. This authority maintains that for machines of from 2000 to 6000 pounds capacity the springs should be the same length, but widths ought to increase with the size of the vehicle. The minimum number of leaves is given as six and the maximum number 12, at least to obtain satisfactory proportioning, the only reason for using leaves in excess of the minimum being the need of meeting the capacity and at the same time keep the plates sufficiently thin that the necessary deflection under a moving load will not set up a strain in excess of the elastic limit of the steel.

The claim is made that it is good practise to use a spring three inches width for a three-ton truck, but it is better practise to use 3.5 inches width, because this permits the use of thinner leaves. That further, a 3.5-inch width spring is heavy enough for a five-ton truck, but a four-inch spring is somewhat safer. In connection with this is the statement that should a spring be made as wide as five inches for this size truck the ends of the leaves would probably be too strong for the centre. In fact, the problem of proportionate widths for springs has apparently not been worked out with care, but there is a limit beyond which increase of width is detrimental to efficiency.

With relation to camber or arc, this authority maintains that front springs ought to be as low as possible because of the effect upon steering, five inches being about the limit, but rear springs can be made with a great arc. Underslung springs have the advantage of greater clearance, but the developed length is considerably greater, and the construction, to have the same capacity, must be much heavier. The strength of the spring is proportional to the developed length, modified by the ratio of camber or arc, but the strengthening of the camber does not compensate for the weakness resultant from the greater developed length. The practical elastic limit of tempered carbon steel is set by one well known maker at 130,000 pounds, and from 100,000 to 110,000 pounds stress is regarded as safe practise. The surge is considered to be nearly double the static strain, and with 110,000 pounds as the limit the static strain is kept between 50,000 and 60,000 pounds. By this is meant that when a vehicle is at rest the steel of the springs may be strained safely to 50,000 or 60,000 pounds, and provision is made for practically doubling this in service. This illustrates the enormous strain upon springs in regular service, and why it is that overloading is dangerous, particularly when road surface and speed are

conditions that materially increase the surge or maximum of stress. Attention has been directed to the fatigue that develops in front springs, earlier than in the rear, which may be due to the fact that the driving thrust and steering stresses are through the master leaves and that the strain is not equal because the forward ends are bolted to the spring horns and the rear ends are shackled. The rear springs are shackled at both ends as a rule, the driving thrust being taken by radius rods, the work done being entirely that of supporting the load.

Note may be made that with a 54-inch rear spring, allowing six inches for the seat, there is a length of but two feet either side of the axle, and the entire elasticity must be provided for in the outer ends of these sections. Greater length would insure slower deflection and reflection, but the spring would necessarily be heavier to afford the necessary strength. The flat spring has less arc or clearance and must be mounted so as to permit movement of the axle, generally outside of the frame. This method of suspension insures a lower body and minimizes side sway. Where the springs are underslung the greater length gives maximum elasticity, but the side sway is increased. The supposition is, however, that the more elastic spring is productive of greater tire endurance, and one authority maintains that there will be 50 per cent. more wear in tires that carry long, easy moving springs. Side sway, because of the lateral movement, is severe on tires, and this is a result to be expected with underslung suspension.

It is maintained by the maker that a flexible spring not only saves the tire, but absorbs the vibration that would otherwise be transmitted to every other part of the vehicle, and other conditions being equal, flexibility, as opposed to stiffer construction, would lengthen the life of the machine by 50 per cent. Maximum elasticity is recommended, the limit being excessive side sway and "bumping". But as the load will vary from 10 to 40 per cent. on the forward springs, and from 60 to 90 per cent. on the rear springs, it will be apparent that springs that will be comparatively easy under load may be exceedingly stiff and hard in action when a vehicle is driven unloaded, and the greater the weight carried on the rear axle the heavier must be the springs and the more the vibratory effect when not loaded. The provision made for the "surge" in excess of the static strain amply explains the reason for the stiff spring when the load is heavy.

Spring proportions are determined in practise by first ascertaining what width may be used, and then what weight is to be carried on each front and rear spring. The deflection allowable under normal load is next found by noting the fibre stress of the steel, making allowance for overload and deflection resultant from overloading. Length is somewhat dependent upon the general practise of frame makers, and width by the general practise of axle makers. When the length and width have been fixed the number of leaves and gauge of the steel are determined by the elastic

nit of the metal used. Proportioning is carefully done because of the necessity of making each part of a spring equally strong, so that no section is strained more than another when in use. One maker points out that when the lengths and widths are known care is taken to make the thickness of the plates such that probable depression will not strain the springs over 110,000 pounds fibre stress unless alloy steel is used, in which event a strain of 150,000 pounds is not exceeded. With this factor of safety the plates are made as thick as possible so as to cut down weight. It is claimed by this maker that the thickness of the plates has nothing to do with the ease of the spring, ease being entirely dependent upon the ratio between the weight and capacity; that longer springs are only used because one can get a greater depression without exceeding the elastic limit. The better the steel the thinner the plates the shorter can be the spring.

TAYLOR MOTOR TRUCK TIRES.

The Major Taylor Manufacturing Company has been incorporated in Massachusetts and will locate at Springfield or Worcester. The company has a capital of \$1,000,000. The officers are: President, Fred L. Taylor; vice president, B. Austin Coates; treasurer, J. W. Grady; secretary, Elbert O. Leonard. The company has acquired the rights to manufacture under the Major Taylor patents and purposes to build tires for motor trucks and heavy vehicles. These will be made in sections and are a spring type, a series of 14 sections necessary for a standard wheel. The tires have been extensively experimented with and are stated to give good results. The factory, if the plans of the project are realized, will have capacity of 100 sets of tires daily.

A schedule of the finances of the Stephenson Motor Truck Company, South Milwaukee, Wis., filed in connection with its petition in bankruptcy, shows that the assets are \$6,833, and the liabilities \$15,576.77. The plant has been operated for several months.

Charles Manager O. J. Woodard of the Woods Motor Vehicle Company, Chicago, Ill., retired from that position Jan. 1, and departed for southern California where he will pass several months before taking up business actively.

Irvin J. Adams, for two years connected with the Chicago Tribune, and who was later associated with the United States Motor Company, the Locomotive Company of America, the copy department of the McElwee Advertising Agency at New York City, and with the American Locomotive Company as advertising manager, has joined the Carl M. Green Company, Detroit, Mich., and will handle the advertising for the Chalmers Motor Car Company, Anderson Electric Company, General Motors Truck Company and other concerns.

MERCHANT & EVANS TRACTOR.

Machine Has Capacity of 4-5 Tons and Can Be Adapted for Horse Vehicles.

The Merchant & Evans Company, Philadelphia, Penn., which is one of the best known firms in America dealing in metal and in high class specialties, has placed in the market a tractor of 4-5 tons capacity that may be utilized with special body equipment, or animal vehicles may be converted for service with it. The tractor is designed for heavy haulage and to be as simple and enduring as is possible for the purpose of economizing care and attention.

The construction has combined the motor, clutch, gearset and jackshaft as an assembly on a dead axle, and the arrangement is such that wheels and axle and all the power plant and power transmission system may be turned as a unit 90 degrees, this permitting the turning of the tractor and the body in a circle with nine feet radius. The tractor is compactly built and despite its weight it is turned readily by the steering column, which, being connected with bevel gears, rotates a worm that engages with the circumference of a large worm wheel attached to the forward part of the main frame, which wheel is concentric of the pivot.

From this pivot a steel frame is extended that is mounted on a dead rear axle, the wheels being fitted with steel tires. The body equipment built for regular service with the tractor has a floor of steel or iron plate, sides of the same material, with stakes from which chain is stretched. The tractor unit is furnished when horse vehicles are to be converted for use with it. Truck bodies and rear axles built for horse service can be adapted for all classes of heavy work, the tractor taking the place of the forward wheels, axle, pole and animals. The tractor is mounted on dual rubber tires and is well sprung. The weight required to afford traction is but 30 per cent. of the weight of the machine and load, and only about 15 per cent. of the load is necessary on the tractor to insure all the power that can be desired.

The claim is made by the maker that the tractor will carry five tons without danger of damage and the weight of the outfit when loaded with five tons does not exceed 15,000 pounds. A tractor has been in use for more than six months and during that period has had capacity to do whatever work has been required without fault or failure. The machine was first displayed at the exhibition of road working machines in connection with the good roads convention in Philadelphia last month.

A factory is to be erected by the Homer Motors Company, Los Angeles, Cal., at San Fernando road and Anvia street, for the construction of heavy tractors and light delivery wagons. The plant will produce all parts required for the construction of these vehicles.

SELLS CLOTHING FROM A MOTOR.**BUYS 50 PEERLESS TRUCKS.****Cleveland, O., Firm Displays Its Goods to Customers in Travelling Showcase.**

A novelty in merchandising is that adopted by Richman Bros. Company, Cleveland, O., engaged in selling men's clothing at retail, which has in service what may be termed a travelling showcase in which are displayed the models of garments sold at different seasons. The firm is well known in Cleveland and vicinity, but it has sought to develop business direct with consumers instead of selling to houses in each locality, and as it manufactures goods, the purpose is to eliminate the profit that is usually taken by the retail merchant.

Doing a mail order business in clothing was found to be a difficult proposition from the fact that the people interested had little knowledge of what they were invited to purchase, other than by catalogue description and illustration, and developing reputation and confidence in competition with local dealers was found to be a slow and unprofitable process.

The company purchased a six-cylinder Peerless chassis and had this fitted with a body that is practically a large showcase, in which on forms are displayed some of the goods that are produced, windows at sides and rear permitting full view of every garment, while the clothing is well protected. The machine was sent out and it has thus far been driven to practically every town and city in northern Ohio, stops being made where the clothing could be conveniently displayed, and a salesman accompanying it talks to those interested.

The machine has attracted attention wherever it has been sent, and business of surprising proportions has been developed in different places with those whom the company expects will become constant customers. The effectiveness of the display has been amply demonstrated, and the purpose of the company is to have another machine with similar body equipment made ready for the spring campaign.

Peerless Car Fitted with a Showcase Body, Used for Display Purposes by a Clothing House of Cleveland, O.

Los Angeles Company Will Abandon Railroad for Direct Highway Shipments.

The opening of the Panama Canal is expected to have a wonderful influence in developing industries and commerce of the Pacific Coast, but the people of southern California are looking forward to especial benefits because of the splendid harbor and terminal facilities at San Pedro, 22 miles distant from Los Angeles, which will undoubtedly make that port one of the most important in California. The shipping from a great section of the United States to Asiatic ports can be done from San Pedro in less time and for smaller cost, and receipts can be received there and distributed with equal facility, while water traffic north from Panama to American and Canadian cities, and vice versa, will undoubtedly call there.

The Motor Truck & Terminal Company of Los Angeles, which is one of the properties of the Perry estate, which also owns the Los Angeles Market Company, has begun preparations for meeting the demands of additional trade, and has bought 50 Peerless trucks of four, five and six-ton capacities, which are to be delivered as quickly as possible. The Los Angeles Market Company has contract to provision all vessels that enter San Pedro harbor, and until now all shipments from Los Angeles were made by railroad. While the distance from city to city is short the cost is comparatively high, and Benjamin Johnson, president of both the market and the trucking companies, believes that there will be a material saving in the use of trucks, eliminating all railroad freights. Besides the freightage the trucking company has contract to distribute to large buyers an average of 20 carloads of fruit and produce that is received daily by the market company, and it is intended to do a general transportation business for Los Angeles business men.

Between Los Angeles and San Pedro the road is well constructed and the machines ought to make fast trips with great regularity, and radiating from Los Angeles to Pasadena, San Bernardino, Monrovia, Redlands, Riverside, Pomona, Santa Ana, Whittier, Long Beach, Santa Monica and Hollywood are 380 miles of fine roads on which motor vehicle traffic ought to be extremely economical. The trucking company will undertake to make general distribution of goods of all kinds that may be received at San Pedro or at the Los Angeles railroad terminal.

The trucking company has purchased the business and equipment of a num-

of small transportation companies and with as the nucleus has inaugurated service will be extended as rapidly as organization can be perfected and the work can be systematized. With the delivery of the 50 Peerless machines the company will have 80 trucks in service, and the cities of the company will be extended in every direction and to such points as conditions shall justify. The Peerless trucks have been ordered fitted with drawbar fitment so that trailers may be used when necessary, the purpose being to use trains of two or three units in the interurban work. The contract requires the delivery of the trucks within 60

The trucks were purchased after a report had been made to Jay Clark, general manager of the trucking company, by engineers who investigated the structural features of the machines and the results accompanied with them in differing conditions of service. The prospect for the future for the company is regarded as very promising, and if the expectations of the resident of the company are realized as many as 100 trucks will be used in haulage between Los Angeles and San Pedro after the volume of commerce passing through the Panama Canal has reached the record.

EDISON BATTERY EXHIBITS.

At the New York and Chicago automobile shows the Edison Storage Battery Company, Orange, N. J., make a very comprehensive display of Edison alkaline-nickel-iron storage batteries for traction, lighting and ignition. Since the last shows the company introduced the A-5 size, with rating of 187.5 ampere-hours, this being intermediary between the A-4 and A-6 sizes, which are rated at 150 and 225 ampere-hours respectively. It is suited for use in 1000-pound delivery wagons, in baggage, freight and industrial work, or where the A-6 size would be larger than was necessary.

Batteries rated at 6.5 volts and 80 ampere-hours, used for ignition and lighting in gasoline vehicles, will be made in steel boxes or wood cases. The electric type of battery affords easy loading and reduces the weight. The Edison batteries are made today practically the same as five years ago, and the same type is used for all purposes, no modification or change being necessary, and the elements are equally suitable in light or heavy traction for lighting plants.

PARCEL POST SERVICE.

Special Body Equipment Necessary to Meet Demands for Vehicle Distribution.

The demands of the public upon the Postoffice Department for the distribution of parcel post packages has enormously increased during the year since this system of delivery was inaugurated, and while the government has purchased but few motor wagons, a large number is used by contractors and rural delivery carriers. The volume of business done by parcel post has grown gradually each week and each month, and during the holiday season that has just ended the number of parcels dispatched was such as to almost overwhelm the facilities of the department, no matter how great provision was made for handling them, and the increase of weight of packages that will be received is expected to very materially add to the volume that will be mailed from now on.

The parcels have been up to the present time comparatively light in weight, although in many instances bulky, necessitating large space in carrying them in vehicles, and great care in handling that they might not be crushed and the contents damaged. Special body equipment is desirable to secure the space necessary, and to afford protection in the event of storms and against loss. An example of a body that is extremely practical is that on a Commerce light delivery wagon now in use in Jacksonville, Fla., for parcel post collection and distribution. This is an express flare-board type, with stanchions supporting a standing roof that is carried forward above the seat to the dash, vertical stay rods strengthening it. Side, rear and front curtains afford protection in the event of storm. The construction is light and enduring, and adapted for handling the freight from the sides and ends. The machine is in constant service and has given entire satisfaction from its practicality and dependability.

Commerce Delivery Wagon Used for City Distribution by the Parcel Post Department of the Jacksonville, Fla., Postoffice.

MOTOR TRUCK "GUN RUNNING".

Daring American Smuggles Arms to Mexican Rebels with a Federal Machine.

An American resident of Arizona, who is the subject of this statement, may not be the only man who has engaged in the hazardous occupation of "gun-running", which is the appellation borne by those who smuggle arms, ammunition, supplies and, in fact, about everything needed by the rebels, across the border into Mexico and turn them over to the rebels—otherwise Constitutionalists. The United States has always frowned upon those who sought to organize filibustering expeditions or engage in attacks or preparations for attack on a recognized foreign government, and severe penalty is always inflicted for violation of the law.

Crossing the border from Arizona one enters the

Federal Motor Truck, Carrying Aeroplane for Use by Mexican Rebels, After Crossing Border, at Agua Prieta, Sonora.

Mexican state of Sonora, and this territory is now in possession of the rebels, but the line is patrolled by United States troops, with absolute authority to make all persons on this side obey instructions. Failure to do so means arrest and abundant trouble. For this reason the "gun-runner" has not only to pass a carefully guarded line, but if he is suspected his movements are constantly under surveillance.

By using a Federal machine this man has not only made trip after trip across the border, but he rushed over an aeroplane that was built by the Glen A. Martin Company of Portland, Ore., that had been sent by train to a station where it was within reach whenever wanted and near to the line. After three months' activities the profits warranted the purchase of a second

machine, and both of these are now used in supplying the rebels the means of carrying on warfare. The statement is made that about 75 per cent. of the ammunition and arms used by the Constitutionalists is shipped on these trucks.

The owner is taking no chances, however, and the governors have been removed from the motors and the machines are equipped with electric lights, so that fast speed can be made at night, when most of the "running" is done. The accompanying illustration was made at Agua Prieta, Sonora, opposite Douglas, Ariz., while the truck and its freight of cased aeroplane was en route to Guaymas, a seaport well down the Gulf of California, but in the State of Sonora.

BIG TRUCK SHOW AT NEWARK.

While there will be no organized exhibition of motor service vehicles in New York this winter, the metropolitan agents will not be denied the business possibilities of display, for those who control New Jersey territory for machines have applied for space at the seventh annual show at Newark, N. J., which will take place at the First Regiment armory in that city the week of Feb. 21. Though the exhibition will be of pleasure cars as well as freight machines, if the desires of the agents for wagons and trucks are met the show will be largely made up of these vehicles. One of the reasons for this is that the Grand Central Palace show will pretty thoroughly demonstrate the passenger cars, and this will be the only opportunity to make a comprehensive display of trucks and wagons. The purpose of the Newark show management is to make the exhibition better than ever before to assure recognition as a state event.

The Breese Motor Plow Company of Wapakoneta, O., recently organized, will begin the production commercially of a tractor especially adapted for farm work, replacing animals for all forms of haulage. The experimental machines have been tested carefully and are regarded as entirely dependable for agricultural service.

The engineering department of the Bessemer Motor Truck Company, Grove City, Penn., is now in charge of R. F. Russell, formerly assistant chief engineer of the American Locomotive Company at Providence, R. I.

The commercial vehicle department of the Motz Tire & Rubber Company, Akron, O., is now in charge of R. O. Brinker, formerly manager of the company's branch at Washington, D. C.

A. L. Longtin, manager of production of the Knox Automobile Company, Springfield, Mass., after 11 years' service, beginning as timekeeper, has resigned. His plans for the future have not been determined.

SIGHTSEEING IN CALIFORNIA.

WILCOX COMPANY EXPANDS.

C¹ Chassis with Special Equipment at Service of Tourists at Pasadena.

Minneapolis Concern Adds \$2,500,000 Capital and Plans for Big Business.

Pasadena, 10 miles distant from Los Angeles, located in the hills and in a region of great fertility, is one of the garden spots of a state noted for its wonderful vegetation and productivity, and a majority of visitors to the southern end of California find its attractions almost irresistible. This city has been made the winter home of people of wealth from all parts of the nation, and these fine estates, as well as the remarkable natural scenery, invite more than usual attention from those who have but little time available. While Pasadena and its environments are beautiful, it would be futile for any person to attempt to see them without assistance, for in whatever direction one goes for miles and miles extend inviting ways and interesting scenes that are all the more interesting when viewed by one who knows of them. For the benefit of the horde of visitors, the Pacific Sightseeing Company was organized and a part of its equipment is a two-ton chassis fitted with a specially built body which will seat 30 persons, there being six transverse

The chassis frame is specially designed and on this body is installed, this being of such width that housings are provided for the rear wheels. On the platform are built the seats, with solid ends and sufficiently spaced to afford ample room. These are large and comfortable, having high backs and cushions. Above the seats, supported on steel stanchions, is a roof. The sides between the dash and the front are enclosed by doors. At either side is a folding glass board, that may be dropped for passengers to get in or leave, which is raised while the machine is running. During storms the body is enclosed by curtains that have large celluloid lights, permitting sufficient light and views by the passengers, but effectively protecting them from the elements.

Regular trips are made, one of which is 40 miles in a circle, and another is a shorter run, which is traversed four to five times daily. During the busy season the machine will average at least 50 passengers and this is often increased by evening runs to special points of interest. The company is in charge of a conductor and a driver, both uniformed. The enterprise is well organized and the machine is a very profitable investment, the operating cost being comparatively small.

The H. E. Wilcox Motor Company has succeeded the H. E. Wilcox Motor Car Company of Minneapolis, has organized with capital of \$3,500,000, and has planned large additions to its manufacturing plant. The H. E. Wilcox Motor Car Company was organized six years ago to produce pleasure cars, but soon service vehicles were built and later on the production was made exclusively of this type. The company developed its market in the Middle West, western and Pacific states, and recently turned to the eastern sections with expectation of materially increasing its distribution. Its authorized capital was \$1,000,000, with \$750,000 common and \$250,000 preferred stock, and those interested were O. P. Briggs, who organized the Twin City Iron Works, which was later absorbed by the Minneapolis Steel & Machinery Company, and who was president for the National Founders' Association, and J. F., H. E. and R. D. Wilcox. The factory has been several times enlarged and the number of employees ranges from 600 to 700.

In the reorganization the above named men have been joined by F. E. Kenaston, president of the Minneapolis Threshing Machine Company; M. J. Scanlon of the Brooks-Scanlon Lumber Company; C. H. Davidson, Jr., of the Davidson-Ross Company; G. W. Lewis of Wilcox Bros. Lumber Company and P. M. Starnes, vice president of the American Timber Holding Company, all well known from their connection with industrial and commercial life of the Northwest. The capital is \$2,000,000 common and \$1,500,000 preferred stock, and the intention is to put from \$500,000 to \$1,000,000 into the business within the next six months. This will be largely used for additions to the plant and for new factory equipment. O. P. Briggs is president of the company, H. E. Wilcox vice president, and the directors include the other names stated.

GMC Chassis and Special Body Equipment, in the Service of the Pacific Sightseeing Company, Pasadena, Cal.

HIGHWAY TRANSPORTATION EXPENSE.

Operating Records of 28 Representative Concerns in Different Cities Show a Saving from 33 to 50 Per Cent. by the Use of Motorized Equipment.

THE cost of transportation practically doubles the value of products of industry when placed in the hands of the users or consumers, this application being made as an average and not with reference to any specific instance, and including every charge from origination to delivery. In one sense this is an accumulation so gradually made that its importance is rarely understood, and only when careful analysis is made is there realization of the enormous burden imposed upon the people. Where an article is of large value the expense of transportation is relatively smaller, and where the cost is comparatively small the ratio is greatly increased. The items of cost may be varied considerably, aside from the charges for transporting, which not only go on forever, but have been increasing because of conditions that have the approval of the people, who, by such approval, justify what must be eventually paid by them.

America is sectional with reference to industrial production, some portions being given over largely to manufacturing, some to agriculture, others to mining, etc., but generally the needs of the people are alike and the products are distributed wherever required. The population is constantly increasing, and consumption keeps pace with this increase. Just so long as the present means of transportation are continued there can be no change unless there be economies worked out by others than the recognized common carriers. There is no doubt that this can be accomplished, but systematic endeavor must be made and whatever the result sought, it must be obtained without loss to those who are now interested in or profiting by any one of the numerous forms of transportation.

Cost by Rail and Water.

Considering the possibilities for a moment, the fact must be borne in mind that during 70 years of railroad development in America the cost of rail freightage has been reduced from 7.66 cents a ton-mile to 7.5 mills, or very close to a tenth of the original cost, yet since 1900 there has been very little change of the average receipts a ton-mile for railroad haulage, according to statistics of the Interstate Commerce Commission, and the prices are slightly more than 13 years ago. Because of these facts there is no reason to hope for relief from the railroads.

Water transportation is materially cheaper than by railroad, as evidenced by available statistics, and shipments from Europe are decidedly less than to Europe, this condition resulting from the cheerful co-operative efforts of the steamship lines, which regulate rates by conference and control the entire Atlantic transportation without the slightest responsibility, so far as jurisdiction of the United States is concerned. The maximum rate will approximate three mills for

ocean lines. Interstate water transportation is decidedly cheaper than by rail, the available statistics showing the rates to vary from .5 mill a ton-mile on the Great Lakes to three mills on canals from five to 10 feet depth.

Factors That Increase Cost.

Regarding these methods even casually it will be noted that these rates must be applied to long hauls and large bulk, and that for smaller shipments the charges are relatively more. But it will be understood that where the distances are of considerable length the cost will increase very rapidly. Considering a manufactured or agricultural product ready for marketing: If there is no railroad siding at the farm or factory the production must be carted to the freight station or to the pier, unloaded and placed in cars or on the vessel. If the shipment is made through by rail or water this is one thing, but there is a possibility that both methods may be used, and in such event this means an intermediate handling. Upon arrival at the destination the freight may be delivered from the car at a siding, but if shipped by vessel there is another cartage, a condition that is met in the absence of spur track facilities. If sent to warehouses delivery may be made to a customer direct, or if shipped there is handling at another terminal and perhaps a second warehouse storage. Or if sent to a store, distribution may be made from there. In fact one could follow a shipment from the producer to the railroad terminal or pier for shipment, through the period of transportation, receiving and handling at the destination, and from wholesaler to retailer and to the consumer. One would necessarily be impressed by the fact that the hauls are exceedingly short and, with the small loads and the time of men and vehicles lost during each stage of the shipment, the cost is very large when distance is considered. Contrast vehicle transportation with rail or water shipments and the rates will be found to be comparatively high. And taking each item one can understand how rapidly the charges for moving multiply.

Hauling Farm Products.

The commercial vehicle committee of the Automobile Chamber of Commerce has given some attention to this phase of the subject and has dealt with facts that are of more than usual interest. In 1906 the Department of Agriculture made a careful investigation of the cost of hauling farm products to shipping points in different sections of the United States, dealing with 23 principal products of farms, plantations and ranches. Nearly 1900 replies were received from correspondents, which were tabulated and analyzed, and from the result the finding was made that the cost was slightly more than 23 cents a ton for every mile hauled

animals and wagons. The average haul was just short of 10 miles, generally over earth or unimproved roads, for that time the percentage of improved roads was a trifle more than eight per cent. From this it will be understood that the average expense of hauling farm products was practically \$2.30 a ton, and this was but the beginning of the charges for transportation. How much more might be added depends entirely upon the market, but this expense might be from three or four times as much in the aggregate, and in the event of long shipments the cost would increase very fast. These products, it will be noted, are not as a rule what might be regarded as valuable and consequently the profit that may be taken is limited. This fact often prevents shipment of freight to points where better prices might be obtained.

Effect of Improved Highways.

The only known manner of reducing haulage cost is by improving the highways, and while seemingly large results have obtained through constant attention for good roads and the expenditure of considerable sums for betterments by towns and states, the percentage of thoroughfares on which the haulage cost is minimized is very small, and whatever gain has been made through improvement has been offset by increased cost of animals, their food and maintenance, labor of drivers and other employees, and other items of expense.

It may be well to note in this connection that whenever price for work is made a rate is established that is paid for all (if the work be done by contract), and not the exact expense to the contractor. And the rate, unless the competition is very keen, is always sufficient to meet a considerable advance. In the cause of the changed conditions there apparently little reason to expect there will be a reduction in haulage cost. As a matter of fact the probability is that there will be an increase rather than a decrease.

Economy with Motors.

There is reason, however, to believe that a substantial reduction of transportation cost can be brought about by the use of motor wagons and trucks. While investigation, such as was conducted by the Department of Agriculture with relation to horse haulage, has been

COST OF HAULAGE AND DELIVERY BY MOTOR AND HORSE DRAWN WAGONS—COMPILED FROM RECORDS OF 28 PROMINENT USERS OF MOTOR TRUCKS AND WAGONS.

made to determine the relative efficiency of motor vehicles, a sufficient demonstration has been made in differing service to state without question that the service would be far more economical than with animals. One can bear in mind that the average haul as ascertained by official investigation was not quite 10 miles, and it is evident that this is a sufficient distance to justify the use of motor equipment. Experience has shown that the economies of power trucks and wagons have in some instances exceeded 50 per cent., and that the average will probably approximate a saving of 33 per cent. This statement is reasonably substantiated by a tabulation made by the secretary of the commercial vehicle committee of the Automobile Chamber of Commerce.

This tabulation is made up from detail reports of operation of motor trucks and delivery wagons used by 30 different concerns in different classes of business in 15 cities, these records in some instances being itemized and covering periods of a year or more, in several cases being the operating cost of from five to 15 or more vehicles. These data were analyzed, tabulated, and arranged to show the expense of delivery and haulage by the day, mile, ton-mile and package, these covering practically all the detail that could be authoritatively determined. Where this was possible the cost of horse service has been placed against the figures for motor equipment, and as the figures for animals were obtained from the owners of motor trucks and wagons and relate to experience with both classes of vehicles in the same work, the comparison made is equitable and reliable.

Average Haulage Costs.

From these figures one will see that the average cost of haulage in urban work with motors is 11.25 cents a mile and with horses 17.75 cents a mile, or a difference of about 36 per cent. The average expense of delivery by department stores, furniture dealers, clothiers, grocers, markets and electric light companies is about eight cents a mile by motor vehicle and about 16 cents with horses, a saving of 50 per cent. with the motorized equipment. The average cost of operating motor trucks and wagons, both gasoline and electric, is \$10.97 a day, this including all items of expense, the garage, driver, interest, depreciation, etc. The average cost of doing equivalent work with horses is \$16.75 a day, which includes the expense of from two to three wagons with drivers. This is a difference of about 34 per cent. These figures bear out the statements made above with relation to the economies of motor equipment, and it will be understood that this work is largely what is regarded as short hauls, where the horse is at its best and the motor wagon shows the least productiveness. In long haul work the probability is that the showing would be increased to 50 per cent.

A suggestion of what the general use of motor vehicles would accomplish is made in estimates submitted by the executive of a Chicago transportation company to the Chicago Association of Commerce. The report stated that more than 250,000 tons of freight

are hauled each day through the streets of Chicago by animal team and motor power, and that this represents a cost of approximately \$60,000,000, or about \$25 a year for each resident of the city. In Chicago more than 50,000 horse wagons and about 4000 motor trucks and wagons are in use, and with the reduction of this number to 20,000 by motorizing there would be a direct saving in haulage cost of from \$20,000,000 to \$30,000,000, or from \$8.25 to \$12 a year for each person, or from \$35 to \$50 a year for each family.

This may appear to be an economy so large that it could not be brought about, but viewed from an intimate knowledge of the possibilities one can affirm that this saving could be considerably increased, because of the relief from street and freight station congestion and the expedition of transportation. Besides this there would be the transformation of stables and barns to more productive purposes and the reduction of the expense of street cleaning, to say nothing of the general betterment of the conditions with regard to the health of the community with the elimination of filth and insects and the generally improved sanitation. What these economies and improvements might save is impossible to estimate.

Present Cost of Living.

Viewed from another aspect, a change in highway transportation throughout the nation would materially affect the present cost of living. There were approximately 24,000,000 horses and mules in the country according to the last census figures, and land equal to the combined areas of Ohio, Indiana, Illinois and Iowa was cultivated to raise grain, hay, straw, etc., to feed them. Careful estimates show that about 25 per cent. of the total value of all agricultural products is expended to feed animals used for haulage. The change from animal to motor equipment for highway and agricultural purposes would permit the use of this immense area for the production of food crops, and gasoline, kerosene, alcohol, distillates and even coal could be used for fuel.

The tabulation, while it is comparatively small, and it does not deal with the agricultural phase of transportation, is worthy the study of every business man, for it indicates there are economies that are sufficiently attractive to be brought about. Incidentally the population of the country is increasing at the rate of 2000 daily, and additional food must be produced to meet the general requirements. The subject is deserving the careful attention of all people, for highway transportation means, besides all its economies, relief from monopoly by corporations through careful organization and systematic operation.

The fleet of General Vehicle wagons that was recently placed in the service of Lord & Taylor, which firm has one of the best known department stores in New York City, is fitted with batteries of A-5 Edison alkaline nickel-iron cells, this size being regarded as having ample power for the service required in delivery work.

BOSTON'S FIRE DEPARTMENT EQUIPMENT.

Reasons Which Have Impelled Delay in Acquiring Motor Apparatus---Recommendations of Chief Mullen as to the Immediate Future--Other Municipal News.

ALTHOUGH the Boston fire department began experimentation with self-propelled motor fire apparatus in 1867, its present gasoline driven equipment is not as large as that of many cities which do not approach it in size. There are several reasons for this situation, and that the fire department officials are thoroughly convinced of the practicability of such equipment is evidenced by the fact that request has been made for an appropriation of \$300,000 for the purchase of motorized apparatus during the next two years.

It will be remembered that the heart of Boston's business district was visited by a most disastrous fire, Nov. 9, 1872. For several weeks previous to this fire the horses of the city had been suffering from an izootic, and the department was seriously handicapped as a result. When the alarm was rung in, there were no horses available for fire duty and the apparatus was drawn to the scene of the conflagration by hand. In addition, the water mains in the district affected were fed by pipes of smaller dimensions, and were themselves in poor condition.

Early Experimentation.

Oct. 1, 1867, Boston first turned its attention to self-propelled steam engines. At that time the Amoskeag people of Manchester, N. H., were experimenting with steam fire engines

of this type, and it would appear that this experimentation was continued under an arrangement with the Boston fire department. One of the new engines was brought to that city and placed in the station at East Boston. Oct. 11 of that year it was placed on trial before the board of fire commissioners. New York City, the members of which came to Boston to see the

novation. At that trial it developed a speed of three miles an hour, and later it was able to traverse the crooked streets down town at a speed of four miles.

This was a steam engine of the second class and its weight was 7000 pounds. The propelling machinery consisted of a stout chain worked in slotted grooves,

and the links were fitted upon the main shaft and hub of the rear wheels, smaller chains being attached to the brake and connected with the forward axle. Subsequently, another engine in the Boston fire department was utilized in an experiment with liquid fuel, or what was known at that time as hydrocarbon for steam engines. An effort also was made to use this fuel for propulsion, but without success.

Self-Propelled Steam Engines.

It does not appear what became of the original self-propeller, but it seems certain that it was not present in Boston during the big fire. However, immediately after that fire, the department turned its attention to the problem once more, in an effort to eliminate the possibility of being dependent upon horses under such circumstances. This machine also was made by the Amoskeag concern and was installed very late in 1872 or early in 1873.

At first this was considered a very satisfactory type, and the machine was in every way similar to that delivered to the department in New York City in 1874. Hartford, Conn., purchased one of the Amoskeag self-propelled steam engines in 1876 and has had it in service ever since. The Boston engine remained in service a number of years, but it became unmanageable on Beacon hill one day and rolled down the grade, injuring a citizen's foot.

Subsequently, the self-propelling chains were removed and it was converted into a horse drawn engine. The city now has two self-propelled steam engines, one purchased in 1897 and the other in 1898.

The conditions which were revealed at the time of the big fire made it extremely necessary that every precaution should be taken to prevent their repetition.

It was for this reason that the department early turned its attention to the purchase of a comparatively large number of steam fire engines. The city now has 48 of these, and they represent a large investment. Other factors have entered into the problem, making it ad-

Chief John A. Mullen of the Boston Fire Department, in His Horse Steam Car, and Apparatus at Headquarters in Front of the Station on Bristol Street.

visible to depend very largely upon pumping engines, and it was not deemed wise to invest in gasoline pumping engines until the practicability of these should be determined beyond question. The water supply also has received due attention.

The Boston fire department now has four gasoline driven hook and ladder trucks, two combination chemical engines and hose wagons, one chemical engine and two tenders. One of these is a Knox machine, and the others American-La France. To these vehicles should be added 24 Buick chief's wagons in service or ordered for immediate delivery, and four Velies. The department also has experimented with Ross steam cars, but these have now been abandoned, and should not be included in the list of equipment in service. Chief John A. Mullen is shown in one of these machines in an accompanying illustration.

Recommendations for Immediate Future.

The time has now arrived where it is believed that it is unwise to delay longer the purchase of additional motor driven equipment. Chief Mullen has recommended the purchase of the following: Nine gasoline pumping engines with capacity of not less than 700 gallons a minute, seven of which are to replace horse drawn equipment; one tractor drawn steam engine; three tractors, to replace horses on three steam engines; 10 combination chemical and hose wagons, to replace horse drawn equipment of the same type; one high powered hose wagon; nine chemical engines, to replace horse drawn chemical engines; two 75 to 80-foot extension ladders, to replace horse drawn box trucks; 11 combination ladder trucks, to replace horse drawn trucks; two tractors for hook and ladder trucks, and three tractors, to replace horses on water towers.

Fire Commissioner Charles H. Cole goes one step further, adding a request that the \$15,000 appropriated

Example 1.

Cost of motor driven combination chemical and hose wagon, \$5500—	
Interest, 5% for one year.....	\$275
Repairs	38
Supplies and tires	390
Total.....	\$703

Example 2.

Cost of motor driven combination chemical and hose wagon, \$5500—	
Interest, 5% for one year.....	\$275
Repairs	315
Supplies and tires.....	574
Total.....	\$1164

Example 3.

Cost of hose wagon, harness and two horses, \$1500—	
Interest, 5% for one year.....	\$75
Repairs, harness and wagon, rubber tires.....	100
Hay, grain, shoeing, two horses.....	400
Total.....	\$575

He adds that, of course, this does not take into consideration efficiency, or the fact that the department gains the services of the driver as an addition to the fire fighting corps.

Repair Shop Service.

The Boston fire department maintains its own repair shop, in a special building close to the headquarters station on Bristol street. This is in charge of Eugene M. Byington as superintendent. He has seen long service in the department, dating from the days of the big fire, and is thoroughly familiar with every piece of apparatus owned by the city. Under his direction many of the steam engines have been completely overhauled and rebuilt. When the automobile equipment first made its appearance he took advantage of every opportunity afforded to learn all about motor vehicles in a practical way. In view of the many factory branches in Boston and the large number of expert automobile workmen engaged in the service stations attached thereto, Superintendent Byington was enabled to secure the assistance of men who had had exceedingly practical experience in this work, and the repair shop is well equipped to care for motor driven apparatus.

It will be understood that the foregoing applies solely to the Boston fire department. Other motor apparatus already is installed in towns and cities comprising metropolitan Boston, and the Boston Protective Association, which virtually is a part of the fire fighting force, soon will be completely motorized. This association is financed

by insurance interests and its duties are to protect goods from damage by water and smoke during the progress of a fire.

The equipment of Boston Protective Association includes one White wagon and a Knox at the Appleton street station, and two Knox machines on Roxbury street. Superintendent Samuel Abbott, who is in command, also has the use of a White roadster. It is expected that two more wagons will be purchased early this year to replace the horses now at the Purchase street station.

White Wagon Installed with Company 2, Boston Protective Association.

for a new fire station at Parker hill be transferred to the purchase of a motor ladder truck and gasoline pumping engine to cover that section from other houses. This last recommendation, taken in connection with the approval of the chief's somewhat extensive list, is of particular interest, since Commissioner Cole reports that the experience of the Boston fire department does not bear out the figures made public from other cities, with respect to the comparative maintenance cost of the two types. He cites the following instances:

A PORTION OF BOSTON'S GASOLINE FIRE APPARATUS.

American-La France Hook and Ladder Truck Installed at Oak Square Station, Brighton Section.

Engine Tender 37, American-La France, Longwood.

Chemical 13, Knox Machine, at Forest Hills Station.

Ladder 29 and Combination Chemical 11, Both American-La France Machines, Located at Lauriat Avenue Station, in the Dorchester District.

Combination Chemical 5 Installed at the Grove Hall Station, Dorchester.

One of the Three Knox Wagons with the Boston Protective Association.

MARTIN FIRE APPARATUS.

Combination Chemical Engine and Hose Wagon Fitted to Type A Chassis.

An accompanying illustration presents the combination chemical engine and hose wagon fitted to the type A chassis made by the Martin Carriage Works, York, Penn. The body work is distinctive in design, and the equipment is such as may be expected to appeal to any city, regardless of size.

The motor is a four-cylinder, four-cycle, water-cooled, vertical unit of the T head type, with bore of 4.75 inches and stroke of 5.5. The cylinders are cast in pairs with valves of ample size for any speed up to 1600 revolutions a minute. The maker's rating is 50 horsepower at 1300 revolutions. Two separate sets of ignition may be used. Lubrication is by force feed.

The transmission is a Brown-Lipe of five tons capacity, and is a unit with the Timken jackshaft, equipped throughout with Timken roller bearings. It

initial step toward the abolition of the last horse drawn apparatus in that city. The three machines ordered at that time will be stationed in outlying fire stations.

New Machines in Rochester—The police department in Rochester, N. Y., which has been using electric vehicles since the abolition of police horses, has advertised for bids for a gasoline driven patrol wagon. The fire department is asking for bids for an 85-foot motor driven ladder truck which will be housed in the new fire station now being erected next door to the municipal garage on Exchange street. A runabout also will be purchased for the use of the supervisor of fire engines.

Test Watrous Engine—The fire department officials in Bridgeport, Conn., have approved the new Watrous pumping engine, which demonstrated its ability to lift 800 gallons of water a minute to a height of 29 feet at the official tests held recently.

In the Market—The following cities are considering the purchase of motor driven fire fighting appa-

Combination Chemical Engine and Hose Wagon Fitted to Type A Chassis by Martin Carriage Works.

affords three forward speeds and reverse. Both axles are of the Timken manufacture. Springs are semi-elliptic all around. Final drive is by roller chains. Tires are 36 by four inches in front and 40 by 3.5, dual, in the rear. The wheelbase is approximately 145 inches and the tread 58 in front and 63 in the rear.

The equipment includes two 35-gallon chemical tanks, 200 feet of chemical hose, 1000 feet of 2.5-inch double jacket rubber lined fire hose, 20-foot rapid rope hoist extension ladder, 12-foot roof ladder with patent folding hooks, two hand extinguishers, lanterns, hose basket, etc.

NEWS FROM VARIOUS CITIES.

Five Police Patrols—The police commission of Providence, R. I., has been authorized to purchase five motor patrol wagons. The city already has two gasoline patrols in service.

Last Horse Replaced—With the opening of bids Dec. 15, the fire department in Pueblo, Col., took the

ratus: Bowling Green, Ky.; Great Falls, Mont.; Ontario, Cal.; Babylon, N. Y.; Winnipeg, Man.; Wheeling, W. Va.; Hastings, Neb.; Napa, Cal.; Rome, Ga.; Aurora, Ill.; Whittier, Cal.; Key West, Fla.; Davenport, Ia.; Washington, D. C.; Fowler, Cal.; Petaluma, Cal.; Canandaigua, N. Y.; Neligh, Neb.; San Jose, Cal.; Livingston, Mont.

Find Conditions Improved—After a reinspection of the city departments in Hackensack, N. J., engineers of the National Board of Fire Underwriters have made public the following findings with respect to the fire department:

The advantages to be derived through automobile apparatus manned by full paid firemen are being fully demonstrated in Hackensack. The number of fires extinguished by chemical streams has been practically doubled, with a consequent reduction in the loss per fire; an increase in the number of full paid firemen would result in greater efficiency and eventually make the fire protection commensurate with the size of the municipality. The improvements in organization and equipment made since the previous inspection constitute a good beginning towards carrying out the recommendations and have increased the efficiency of the department; the results merit a further increase in the full paid force and the addition of automobile apparatus along the lines of the recommendations of the previous report.

LONDON'S GASOLINE-ELECTRIC OMNIBUSES.

Brief Description of Tilling-Stevens Chassis Operated by Thomas Tilling, Ltd.—Methods Employed in Providing Care and Maintenance—Cost Analysis.

By R. Douglas-Vickers.

THE great development which has attended the operation of motor omnibuses in England has brought to the front a very interesting type of vehicle

signed so that any increase in the demand for current when the engine is fully loaded is accompanied by a corresponding reduction in voltage.

The output in kilowatts at any speed is proportional to the power exerted by the engine, but the volts and amperes may vary over a large range according to the gradient, speed, or degree of acceleration required. The amperes required by the series wound motor are nearly proportional to the voltages of supply. It thus follows that when the vehicle is running on the level road the demand for amperes will be small, but on gradients it will considerably increase, with a corresponding decrease in voltage, resulting in a slower speed with increased torque; this change takes place automatically.

On level roads and ordinary gradients the whole of the control is effected by the gas throttle pedal operated by the right foot of the driver. On stiff gradients the shunt resistance has to be employed to allow of increased engine speed. The controller has three positions, forward, neutral and reverse, the whole of the speed regulation being effected with the one position of the controller. As the generator ceases to excite at 300 revolutions a minute of the engine, it is not necessary to break the circuit between the dynamo and the motor on stopping in traffic, as by the release of the throttle pedal and the consequent slowing down of the engine no power is transmitted to the cardan shaft.

In other respects the Tilling-Stevens chassis more or less corresponds to the usual type met with.

A large number of motor omnibuses of this type are now in service, both in the United Kingdom and elsewhere, but I only propose referring to the fleet

Type of Tilling-Stevens Omnibus in London Service.

of the Tilling-Stevens, and some notes regarding it will serve to preface a short account of its work under service conditions.

The great feature in the design of the chassis is the elimination of the usual clutch and gearbox and the substitution therefor of a flexible electrical transmission between the gasoline engine and the driving wheels, which gives, among other things, remarkably easy starting and control, and silent running. The final drive in this vehicle is from an electric motor through a cardan shaft to the worm gear on the back axle. The electrical supply for the motor instead of being provided by a battery, as in the ordinary electric vehicle, is supplied by a specially constructed dynamo coupled directly to the four-cylinder gasoline engine, which is the main source of power.

The electrical portion of the mechanism consists, therefore, of the generator, a series wound electric motor, and the controller box, the last mentioned carrying a reversing switch and a shunt resistance for the generator fields. The generator, which is capable of an output of from one to 20 kilowatts at speeds varying from 350 to 1400 revolutions a minute at a voltage varying from 0 to 300, has been de-

Tilling-Stevens Omnibus Chassis with Body Removed, Showing Gasoline Motor.

Plan View of Tilling-Stevens Chassis, Indicating Location of Electric Dynamo.

operated in London by Thomas Tilling, Ltd. By the end of the present year (1913) this concern will have about 175 machines at work in London.

In order to keep the vehicles in continuous and efficient running order the following garage methods are adopted: Each omnibus is retained in the garage every 14th day and thoroughly inspected; that is, the valves are ground in and adjusted, the magneto carefully examined, the brakes adjusted and renewed. The electrical equipment is also examined and cleaned. Every eighth inspection day the differential, including the worm and worm wheel, is taken out of the back axle and thoroughly examined for any wear that may have taken place, this work being done in addition to that already mentioned. No work is done at night beyond ordinary brake adjustments, with the exception of the daily washing, cleaning and greasing. At the end of a year's working each vehicle is taken to the company's chief garage and the chassis thoroughly overhauled, the body being taken to the coach building department, where it is overhauled and repainted.

Referring back to the fortnightly inspection: The "Driver's Report and Shed Day Sheet", relating to the omnibus garaged, is taken out of the binding case and attached to the machine, the points mentioned thereon are ticked off as the examination is proceeded with, the omnibus being finally tested by the garage superintendent, who signs the sheet before the vehicle leaves the garage.

Naturally, a very complete record of all expenses is kept in connection with the operation of this fleet of omnibuses, and I am able to give the proportion for

each item a mile travelled.

It might be mentioned in conclusion that each of these omnibuses covers upwards of 120 miles a day, and that lost time through mechanical stoppages is practically an unknown quantity. What it costs to produce a model London type of motor omnibus is not generally known, but it is in the immediate vicinity of \$960, which admits of easy

amortizement in five or six years.

In addition to this information concerning the Tilling-Stevens chassis, supplied by Mr. Douglas-Vickers, it may be stated that the gasoline engine has four cylinders, with bore of 105 mm and stroke of 125 mm (4.13 by 4.82 inches), giving a rating of 27.25 horsepower under the R. A. C. formula, which is the same as that of the S. A. E. in this country. The cylinders are cast in pairs. Cooling is by water, and further assisted by a disc fan carried on the rear end of the dynamo shaft, the motor and dynamo being of the semi-enclosed type. This shaft, as well as the motor shaft, is mounted on ball bearings. Lubrication of the motor is by a splash system. Ignition is by Bosch high-tension magneto, and the carburetor is a Solex.

EXPENSES FOR TILLING-STEVENS 'BUSES.

	Cents a Mile		Cents a Mile
Running	1.736	Depreciation, rent rates	1.698
Maintenance480	and taxes302
Tires	2.196	Trade vehicles	1.694
Gasoline	2.134	Conducting470
Lubricating oil156	Body upkeep540
Driving	2.502	Traffic expenditure002
Grease036	Men's uniform	
Kerosene042		
Lighting138	Total	14.126

As stated above, a prominent feature of the design is the mounting of the dynamo, which is connected direct to the engine by means of a flat leaf spring coupling, no friction clutch being used. The control is effected entirely by the gas throttle pedal, except when ascending very steep hills, in which case a shunt resistance contained in the controller box is used, allowing increased engine speed.

New Commercial Car Accessories

Kellogg Engine Primer.

The Kellogg Manufacturing Company, Rochester, N. Y., is making a new form of engine primer which presents novel features, in that the device is mounted on the driver's side of the dash and the container or vessel is of the self-filling type. The fluid receptacle is of glass and is fitted with two knurled nuts or valves, the upper being employed to fill the vessel while the other controls the flow of the priming fluid to the motor. The fuel supply is obtained by turning the top knurled member to the left, the gasoline being forced from the tank to the glass member by the vacuum created by the suction stroke of the piston of the cylinder. It will be noted that two small pipes are attached to the dash vessel, and these are run from each arm of the intake manifold, thence directly over the intake valves of the cylinders. Operating the lower knurled nut permits the fuel to flow over the valves and at the same time the fluid is mixed with the incoming air drawn in through the carburetor when the motor is cranked. This assures a rich mixture for starting and one of the qualities of the primer is that the flow may be so controlled as to provide a slightly rich mixture until the engine is warm enough to operate on the normal mixture. The company also manufactures a model for pressure feed fuel systems.

Brown, Jr., Tire Pump.

The Brown Company, Syracuse, N. Y., maker of the Brown power tire pump, has brought out a new design termed the Brown, Jr., which is moderately priced and designed for light vehicles. It is identical in all respects, save the size and length of hose, and is not equipped with a gauge. The pump operates on the compound principle, inflating the tire with pure, cool, fresh air, and it is stated that a shoe can be pumped up to a pressure of 60 pounds in a few minutes, or to 150 if desired. The cylinders are of gray iron, bored and reamed on special machines, and the finish is two coats of gray enamel. The same high grade material and workmanship characteristic of the product of the concern are incorporated in the new design. For \$1.50 extra the company will supply its Q. D. spark plug and special attachments, including a pump connection.

Sure Start Electric Vaporizer.

The United Motor Equipment Company, Chicago, is marketing, through its sales agent, W. E. & J. H. Dodson, the Sure Start electric vaporizer, which is a compact device weighing 10 ounces, and which increases the temperature of the fuel by the use of electricity. It is attached in proximity to the intake manifold, this being tapped to connect a tube conveying the vapor, which is drawn into the cylinders in the usual manner. A small switch is mounted on the dash and controls both the supply of fuel and the electricity which is taken from a six-volt battery. The maker states that it requires but a few seconds for the current to increase the temperature of the fuel to a point making for rapid vaporization.

E-Z Rim.

The E-Z Rim Company, 146 Summer street, Boston, is marketing the E-Z rim, which the maker states can be applied to any automobile wheel using pneumatic tires, without alterations and at a moderate cost. It provides the advantages and conveniences of the quick detachable rim, and, as will be noted

by the accompanying illustration, the use of split rings, cams, levers, etc., is eliminated. The E-Z comprises a removable ring to which lugs are fitted, these retaining it to the rim proper by means of bolts. The method of retention is similar to that employed with demountable types, six nuts and bolts anchoring the ring to the felloe. One of the qualities of the E-Z is that no tool, other than a brace wrench supplied with each equipment, is necessary to remove and replace a tire. With the E-Z the clincher type of shoe may be utilized until worn out and replaced by quick detachable, a universal arrangement. The company manufactures a rim for the model T Ford commercial car, which is fitted with clincher rims.

Dover Breech Lock Oiler.

The Dover Stamping & Manufacturing Company, Cambridge, Mass., is offering to the trade the Dover wide mouth breech lock oiler, a new design, which makes for convenience in that the spout may be easily and quickly removed by a rotating movement. This permits of replenishing the supply of fluid without spilling, as the opening is ample in size. The oiler is practically a one-piece construction, the bottom being of the best clock spring steel, pressed against the shoulder of the dome, and the seam is double turned. The spout and breech are put together in the same manner. No cement, solder or brazing is used in the construction. The oiler is made of the best cold rolled steel, brightly polished, plated and lacquered, and is designed to withstand severe use. It is made in 10 sizes, Nos. 12 to 15, these having capacities from three ounces to one pint.

Kent Pocket Meter.

The Atwater Kent Manufacturing Works, Philadelphia, is marketing the Kent pocket meter, which is an automatic volt-ammeter for ascertaining the condition of dry cells and storage batteries. The instrument may be utilized for testing the amperage and voltage, and the readings are accurate, as the needle is delicately pivoted. One of the qualities of the instrument is that no change is made in the connection to the battery for reading voltage and amperage, as the latter is obtained by pressing a button. A flexible lead of ample length is provided with each meter, which is of the dead beat type, insuring accuracy. The Kent comes in a neat, hand sewed leather case and is calibrated for both volts and amperes. Another of its features is the use of a substitute for glass, the maker stating that it is unbreakable.

Mosler Vesuvius Spark Plug.

A. R. Mosler & Co., Mount Vernon, N. Y., well known to the industry as the maker of the Spitfire spark plugs, is marketing the Vesuvius plug, which is designed to withstand severe service. The centre core is of a special stone, practically indestructible, and one of its qualities is that it is so shaped and constructed as to be absolutely gas tight. Another feature is that the plug may be readily disassembled and the parts replaced without interfering with the original adjustments of the points. The last named are of genuine platinum, liberal in size, making for efficiency and durability. The Vesuvius plug is made to fit any motor and is manufactured with various threads, etc. The same high grade material and workmanship for which the product of A. R. Mosler & Co. is noted, are incorporated in the new design. The company issues a booklet on spark plugs which will be mailed free on request.

Illustrating Some of the More Recent Accessories Designed for the Commercial Vehicle, Repair Shop and Service Station.

THE A B C OF MOTOR TRUCK IGNITION.

Part XVII---The Construction and Operation of the Types of Bosch Magnetos Having Double-Wound Armatures---Features of Independent, Dual and Duplex Systems---Single and Dual Contact Breakers---Wiring Diagrams.

By C. P. Shattuck.

BOSCH magnetos are well and favorably known, both in this country and abroad, being standard equipment with a large number of makes of commercial vehicles, and

constructed for service with single and multi-cylinder motors. The various forms are classified by letters and numbers, the letter designating the type of model, while the figure usually represents the number of cylinders. For example: Types D3, D4 and D6 are constructed for service with three, four and six-cylinder motors.

Fig. 94—Bosch ZR4 High-Tension Magneto, Which Is an Enclosed Construction.

With the exception of the number of metal segments the distributor plate, ratio of drive, etc., the principle of the various types is the same. The mechanical details, however, vary slightly.

Various Types Defined.

The terms utilized by the commercial car manufacturer in defining the ignition system employed with his product are often confusing to the novice. The expression high-tension is universally used because with a few exceptions the jump spark has replaced the make and break. Technically, the writer holds that the term high-tension cannot be applied to a magneto generating a low-tension current and using an induction coil for transforming the electricity into a high-tension current, a contention borne out by at least one maker who defines his product as a low-tension magneto employing a coil to convert the current to a high-tension. Distinction is often made between the low and high-tension types by referring to a magneto with a single wound armature as a high-tension, and that with a double winding (primary and secondary) as a true high-tension.

Dual Systems.

Many persons do not understand the meaning of the term dual in connection with the ignition system of a motor. It is generally employed to convey the impression that two sources of current are available, and when utilized in such manner is correct. For the purpose of simplifying the application of the term in

this discussion, it will be referred to as dual and true dual. The latter is an ignition system, including two separate and distinct units, such as a set of dry cells or battery, timer or commutator and induction coil, providing a high-tension current to one set of spark plugs, and a magneto supplying electricity to another set of plugs. This arrangement provides two independent systems, either one of which may be utilized and not be affected by the failure of the other.

Dual Contact Breakers.

The dual system comprises a magneto, the circuit breaker and distributor of which are employed to break and distribute the battery current. With this system the primary current is transformed as previously explained. Generally the circuit breaker of the magneto is employed for interrupting both the primary current of the instrument and that from the battery, although some makers provide a separate contact breaking mechanism in the magneto, a construction that is held to obtain two independent forms of ignition.

Operation of Bosch Magnetos.

The Bosch magnetos discussed herein are all of the true high-tension type; that is, the armature carries a double winding, as will be noted by reference to Figs. 97 and 100. The D4 magneto shown at Fig. 102 is also a true high-tension instrument. At Fig. 98 is presented a diagram of the principal parts of the Bosch D4, and a little study should enable the reader to un-

Fig. 95—Bosch DU4, Independent Type with Variable Advance, and Constructed for Multi-Cylinder Motors.

derstand the mode of operation. The principles involved can be applied to other types made by the company. To simplify matters, especially the wiring, the armature is shown separately. It should be borne

Fig. 96—Contact Breaker Mechanism of Bosch DU4 Independent Type Magneto.

in mind that the current produced in the armature winding is obtained twice each revolution, or at intervals of 180 degrees rotation. This provides a spark each half-revolution of the armature of a four-cylinder instrument.

Path of Current.

The armature is of the shuttle type and has two windings. The primary or coarse windings are indicated by the lines C 1, while the secondary or fine wires, of which there are many more in proportion to the others, are designated by C 2. One end of the primary wire is connected to and is grounded to the armature core, and the other end passes to the insulated part of the interrupter. With this construction the separation of the contact points is obtained by the cams of the interrupter mechanism, which is attached to the armature shaft and revolves with it. The interrupter lever, so-called, is pivotally mounted, and carries a platinum point which normally is in contact with a fixed platinum point. These are designated in the drawing as g 3 and g 2 respectively. The last named is adjustable, so that the distance between the

points may be varied to obtain the break or interruption of the primary current when the greatest number of lines of force are being cut. Or, in other words, when the greatest amount of current is being obtained.

Flow of Primary Current.

Normally, the platinum points are in contact, and when together the primary circuit is closed. Upon the armature shaft being rotated the contact is broken by the lever coming in contact with the fibre rollers, which are shown at C, Fig. 102.

The arrangement of having a revolving contact breaker mechanism and stationary cams permits of the conducting of the current from the primary coil to the interrupter by a direct connection, eliminating brushes that would otherwise be necessary.

When the platinum points are together, the currents generated in the winding have practically no effect on the secondary coil, because the primary winding is short circuited upon itself, flowing through the conductor "f" to the insulated member and thence back to ground through the grounded contact lever.

Secondary Current.

The arrangement of the secondary winding is also outlined at Fig. 98. One end is secured to the live end of the primary, where it joins the conductor leading to the insulated contact point g 2, while the other is coupled to the collecting ring carried by the insulator at the driving end of the armature. A carbon brush collects the high-tension current, and by means of the conductor "1" is delivered to the revolving brush of the distributor n l.

Proper Time of Break.

When the contact points are together, providing as they do a short circuit for the feeble currents induced in the primary, there will be no production of high value current in the other winding. This contact is maintained until the armature attains a position

Fig. 97—Sectional View of Bosch DU4 Magneto: A, Depicting the General Arrangement of the Components; B, Distributor End of the Instrument.

Fig. 96—Diagram of Principal Parts of Bosch DU4 Magneto, Showing Mode of Operation and Principle Involved.

where the current reaches its maximum value, when the contact points are separated, breaking the short circuit that existed during the contact period.

The secondary circuit has been open during this time, or during that period when the distributor arm is moving from one contact to another, and there has been no flow of energy through the secondary winding. While the energy of the secondary is augmented, a spark will not occur at the spark plug until the contact points of the breaker mechanism separate. This is usually true if the distributing brush is in contact with a segment of the distributor. From the above may be deduced that a spark of sufficient value to ignite the mixture cannot be obtained unless two conditions exist. First, the armature must be in a position insuring maximum current production; second, the contact points must separate when the secondary current has attained sufficient value to overcome the resistance of the air gap between the plug electrodes. The function of the safety spark gap, distributor, condenser, etc., has been previously outlined.

Bosch DU4 Contact Breaker.

A variation in the design of contact breakers is illustrated in the construction presented at Fig. 96, which illustrates the components of the type used with the Bosch DU4 magneto. The mechanism is attached to the armature shaft and revolves with it, but differs from the type above described

in that the interrupter lever makes contact with two steel segments secured to or practically integral with the interrupter housing.

The interrupter lever is rotatably mounted and its platinum screw is in contact with a similar or fixed member. Upon the armature shaft revolving, the fibre block comes in contact with the steel segments, depressing the interrupter lever and consequently

separating or breaking apart the platinum contact parts. The housing of this design, which is termed the independent type of magneto, may be rotated, providing a timing range of 35 degrees. For example: With the timing control arm in a fully retarded position, it could be so moved as to obtain an earlier break or separation of the contact points. This is obtained by rotating the housing in a direction opposite to that in which the armature shaft is revolving, causing the fibre block to make contact earlier with the steel segments.

DU4 Independent Type.

The Bosch DU4 independent type magneto, is a true high-tension instrument, and a longitudinal sectional view is shown at Fig. 97 A, with the principal components lettered. The grounded end of the primary winding is connected to the armature core, and the other, or live end, to a brass or connection plate. A screw extends through this plate and serves both to retain it and to conduct the primary current to the contact block. Both the screw and this block are insulated from the interrupter disc, which is in metallic connection with the armature core. The operation of the circuit breaker mechanism has been explained.

The grounded end of the secondary winding is connected to the live end of the primary, and the other end of the secondary is led to a collector or slip ring. Contacting with the collector ring is a carbon brush, retained by a holder. The high-tension current is conducted to a terminal piece, thence through a conducting bar to the central distributor contact. Thence its path is to the distributor carbon brush, which rotates with the distributor gear. Fig. 97 B shows the distributor gear, carbon brush and current conductor, also the proportions of the driving and driven gear, that of the armature and distributor respectively. It will be noted that the driven gear makes one revolution to two of the smaller member, and with the four-cycle, four-cylinder motor, it rotates at the same speed as the camshaft. The driving gear and armature shaft rotate at crankshaft speed. With the DU4 type of magneto the wiring plan is the same as with all true

Fig. 99—Dual Contact Breaker of Bosch ZR4 Magneto with Components Lettered.

high-tension instruments. The method of grounding the primary current for stopping the operation of the motor, has been fully explained.

ZU4 and ZR4 Magnetos.

The Bosch ZU4 and ZR4 instruments are very similar, the former being slightly smaller and varying in a few mechanical details. A longitudinal sectional view of the ZU4 is presented at Fig. 100. The ZR4 dual magneto is illustrated at Fig. 94 and like the ZU4 is enclosed construction, preventing the entrance of water and foreign elements, which impair the efficiency of magnetos.

Both the ZU4 and ZR4 are designed for service with four-cycle, four-cylinder motors, also with two-cycle engines, being driven at crankshaft speed with the four-cycle and double that speed with the two-cycle. By referring to Fig. 100 A the enclosed features of the ZU 4 will be noted. It will be seen that the carbon holder, brush collecting the high-tension cur-

rent is made with a dual contact breaker, which construction is illustrated at Fig. 99. Its details are different from the DU4 and other independent types of magnetos in that a second lever is located under the contact breaker housing in a separate housing, its function being to interrupt the battery current. Its mechanism is independent of the magneto contact breaker, but the interruption of the battery and magneto circuits is simultaneous.

Transformer Coil Utilized.

A transformer coil is utilized with the battery system of the concealed dash type, and with the switch lever thrown to the battery side, and with the motor operating or being cranked, a spark occurs as the battery circuit is broken by the battery interrupting mechanism. To permit of starting from the seat, assuming, of course, that the cylinder is filled with a mixture and on compression, the coil is provided with a vibrator which is operated by pressing a button. The

Fig. 100—Sectional View of Bosch ZU4 Magneto, Illustrating General Arrangement of Parts; B, Outlining the Contact Breaker and Distributor.

rent and safety spark gap, etc., are completely enclosed.

Timing Window.

One of the features of the instrument is the incorporation of a timing window, making it possible to ascertain at a glance the segment with which the distributor arm is making contact. This eliminates the trouble of removing the distributor cover when resetting and timing the instrument after it has been removed from the motor. With the new method, it is a simple matter to rotate the armature shaft until the figure 1 appears in the timing window. The terminals are also of an improved type. Throughout the ZR types are noticeable for their compactness, high standard of workmanship and accessibility of parts subject to wear in the normal course of operation.

ZR4 Dual Contact Breaker.

The Bosch Magneto Company produces instruments providing dual ignition, also a two-spark magneto, and a dual two-spark ignition system. The ZR4

action results in a spark regardless of the contact breaker lever position.

The Bosch duplex system, the wiring plans of which, with three and four terminal coils, are presented at Fig. 101, provides two sources of current, either of which may be utilized independently of the other, and in connection with one set of spark plugs. The system includes a primary coil combined with the switch. The latter carries a press button which when operated with the lever at "battery" permits the motor to be started on the switch, provided, however, the cylinder is charged with gas and the motor has not stopped in such position that the contact breaker points are closed. This does not generally occur in practise.

It will be noted that the interrupter cover is provided with two binding posts. The method of wiring requires that the positive terminal of the battery be connected to one of these posts and the negative to the other. Two brushes are utilized in the circuit

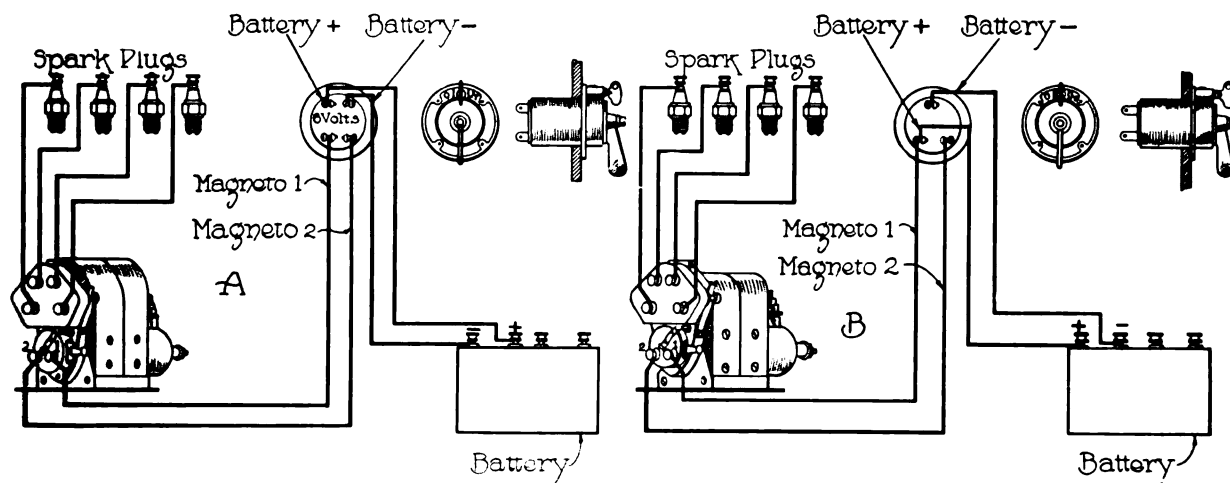

Fig. 101—Wiring Plan of Bosch Duplex Ignition System: A, Showing Method When Coil Is Equipped with Four Terminals; B, How Wired When Three Terminals Are Utilized.

maker housing and the disc or cover to which the segments are secured is provided with two metal segments. When one brush, A for example, is in contact with the segments to which the positive terminal of the battery is connected, the battery current will flow to the carbon brush, through the interrupter points and back through the other brush and post to the negative of the battery.

When the interrupter is closed it forms a path across the segments and the breaking of this short circuit by the opening of the interrupter points results in the production of extra current in the primary coil. The direction in which the extra current will flow will be the same as that of the magneto current and it will complement and intensify it. A half revolution of the nature shaft will bring the other segment in contact with the brush A, and the conditions will be such that the flow of the battery current will be reversed to coincide with the reversal of the magneto current. With the battery properly connected every alternation of magneto current is accompanied by a reversal of the battery circuit. The wiring plan at Fig. 101 clearly shows the arrangement of the system. One of the peculiarities of the duplex system is that the battery

and magneto are connected in parallel and not in series, as with the usual transformer coil system.

Wiring of Cells.

The coil is wound for six volts, and a six-volt storage battery is recommended. Dry cells may be used, however, but 10 must be employed, these being divided into two groups of five each, each group being wired in series and the two sets connected in parallel.

The Bosch independent type magneto may be utilized in connection with a double system of ignition; that is, by utilizing two sets of spark plugs and employing a timer and a coil of the vibrator type, or a timer-distributor and coil, for supplying one set of plugs, and the magneto for the second set. The Bosch vibrator is utilized for starting on the spark, and depressing the starting button causes a constant streak of sparks to flow between the points of the spark plug as long as the depression continues and the distributor brush of the secondary timer is in contact with a segment leading to a spark plug.

(To Be Continued.)

Ed. Note—The next installment will deal with the construction and operation of the Eisemann magnetos.

Fig. 102—Bosch DU4 True High-Tension Magneto: A, Driving End; B, Longitudinal Section; C, View with End Cover Removed.

HINTS FOR PROPER MAINTENANCE.

A GRINDING machine is practically an indispensable tool in the equipment of the repair shop or private service station, but some establishments,

Grinding Attachment for Lathe, Permitting of a Variety of Internal and External Grinding.

especially the smaller ones, send work requiring grinding outside. Some machinists display considerable ingenuity in constructing grinding attachments for the lathe and an accompanying illustration presents a plan, the inventor of which was awarded the weekly prize by the Commercial Motor, an English publication.

It will be noted that the design does not employ a floating countershaft. With it the inventor claims he is able to grind hardened steel spindles, camshafts, crankpins, valves, cylinders, etc., and states that in planning the attachment considerable thought was given to have the equipment as rigid as possible and that all parts operated on it should be ground quite circular.

The maker states that the attachment can be used either for grinding internal or external work and that it can be fitted easily to the ordinary lathe. The left hand figure shows the end elevation, and that at the right the grinding spindle and method of attaching it to the tool clamp of the top portion of a compound slide rest. The smaller figure shows a plan of the grinding arm itself, which is somewhat after the style of a Landis grinder. The attachment can be made fairly easily, but if desired can be purchased. For internal work it is provided with a long arm, but for external work the latter is only about three inches in length.

A small pulley for driving the arm is seen located between two bearings, so that it will be realized that there is no overhang to set up vibration. The method of driving the spindle consists of a pair of hangers placed in front of the ordinary overhead shop shaft, and about central with the lathe, so that the attachment can travel about six inches on either side without materially altering the relative position of the driving belt.

The driving drum consists of two 12-inch diameter pulleys about two inches wide. These are placed about three feet apart, and then lagged with strips of

wood one inch in width, these being placed lengthwise and attached to the pulleys by means of set screws. The whole is then skimmed up in a lathe, and it will be found that this makes quite a nice light overhead drum, which gives nearly three feet of travel over the grinding wheel. The small pulley is so arranged that it may be driven off the existing cone pulley on the overhead shaft which drives the lathe. By this means a good increase of velocity is given by the emery wheel.

The cut is put on by means of a cross fed screw in the lathe saddle. If a taper movement is required the top rest is, of course, set to taper just as if one were going to machine taper in the ordinary way. The maker of the attachment states that he considers the rig simple; that it will provide accuracy in grinding, and can be fitted by any average machinist.

SECURING BRASS PIPE IN VISE.

In replacing a broken brass pipe with new, and when threads have to be cut, the walls will be crushed unless one utilizes caution. A device for securing the work may be made by taking two pieces of wood and boring a hole in the line where they are joined together. The pipe is then placed between the jaws in the half-round holes and clamped tightly in the vise. A little powdered resin applied to the wooden members will prevent slipping.

INCREASING CHUCK CAPACITY.

In the overhaul of the truck it is possible that some machine work will be required that will need a larger chuck than that with which the lathe is equipped. In an accompanying illustration is presented a suggestion for increasing capacity of chuck.

It will be noted that to increase its radius, four extra blocks are machined and rectangular holes provided to enable them to be fitted over the standard

Suggestion for Enlarging Capacity of Lathe Chuck by Fitting Additional Jaws.

jaws. It is stated that in a lathe having a capacity of 10 inches the additional jaws will permit of work up to 14 inches being turned.

GARAGE AND SERVICE STATION EQUIPMENT.

THE Kellogg Manufacturing Company, Rochester, N. Y., maker of the Kellogg four-cylinder power pumps, is marketing the Kellogg electric motor

Kellogg Electric Motor Driven Garage Pump and Tank.

driven garage pump shown in an accompanying illustration. As will be noted, the pump, electric motor and storage tank are mounted as a unit.

The pump is a heavy duty, water jacketed, four-cylinder unit, powerful and compact, and may be connected direct to the tire or to the tank, where air

can be stored at a pressure of 150 to 200 pounds a square inch. A water tank is provided, the fluid circulating around the head of the cylinders of the pump, thence to the reservoir on the thermo-syphon principle. The rings of the pump are of babbitt and the connecting rods of bronze. The pistons are of anti-friction metal. It is leak proof by the company's exclusive cup wash construction. The cams are drop forged steel, carefully ground to size. Lubrication is by the splash method.

The electric motor is .25 horsepower capacity and is operated by silent chain. A knife switch regulates the rotation of the motor, and connected with this is a simple automatic air release, which permits the motor to attain full speed before receiving the full load. The maker states that this eliminates troubles experienced with fuses.

Two gauges are provided. One, conveniently located, indicates the exact air pressure in the storage tank, which is tested under 500 pounds pressure to the square inch, and the other is incorporated in the tire

The platform on which the equipment is mounted is fitted with rollers, permitting it to be moved about the garage or to the sidewalk when a tire is to be inflated with air stored in the tank. As previously mentioned, shoes may be inflated from the pump direct if desired.

The motors are supplied for either alternating or direct current, and when the former is to be used it is essential to state the number of cycles. In considering the installation of the equipment the maker states that it is important that the voltage be known that the motor must receive its full number of volts if efficiency is desired. The Kellogg equipment comes complete or without the tank. The Kellogg Manufacturing Company will supply complete details on re-

quest. This concern also manufactures power air pumps.

HEALY VALVE RESEATER.

The Healy valve reseater and dresser is manufactured by the Healy Tool & Appliance Company, Brocton, N. Y., with New York office at 1790 Broadway, of which Ralph Walcott is manager. The complete equipment is shown in an accompanying illustration with the components lettered.

A bearing on the valve stem is provided at A, it being in the same relative position as to seat as is the bearing in the cylinder. This bearing coming so near to the valve head eliminates chattering while the valve is being dressed. A second valve stem bearing is provided at B, it holding the stem central and rigid while a cut is being made. The adjustable bearing handle is shown at C and it may, by a few turns, be adapted to any size valve stem or worn members.

The reversible face cutter D has a 45-degree cutter at one end and a 60-degree at the other. These being adjustable, a roughing cut may be first used, then a finishing cut, without disturbing adjustments.

The adjustment of the face cutter is depicted at E. It can be set to the thousandth of an inch. The seating cutter F is so shaped that it will remove all shoulders. The cutter carrier G has a taper which corresponds with that of the cutter, aligning it perfectly in the carrier. A Brown & Sharpe taper to the pilot aligns the same perfectly with the cutter, as shown at H.

The tool is operated by hand; all wearing parts are of tool steel, hardened and ground to exact proportions, and the equipment comprises a dressing head

Healy Valve Reseater and Dresser, a Complete Equipment.

complete with an extra roughing cutter, also one each of 1.625, two, 2.25 and 2.5-inch valve seat cutters and carriers. The pilots are: .3125, .375, .4375 and .5 inch.

CORRESPONDENCE WITH THE READER.

Testing for Auxiliary Air.

(54)—In the instruction book of the truck I drive it says: "Be careful in replacing the motor gaskets so that auxiliary air will not be admitted". What is the cause of it and what

**Fig. 1—Probable Causes of Auxiliary Air Indicated by Arrows
—Worn Valve Guides Are Also Responsible for Extra Air.**

are the effects? In what other places may auxiliary air be present?
DRIVER.

Boston, Dec. 28.

By auxiliary air is meant extra or additional air. It should be borne in mind that the mixture is obtained by mingling so many parts of air with one of fuel, this being performed by the carburetor, and taking place when the piston descends on the intake stroke. This suction stroke draws air through the carburetor, mingling it with the fuel, and the resultant mixture is sucked into the cylinder.

Any openings between the carburetor and the cylinder will permit of extra or auxiliary air being taken in, which results in diluting the mixture; that is, weakening it. If the proportions of air in the first place were correct, the additional air generally will create such a lean mixture that it will not ignite easily. Usually the motor will miss at low speeds. but operates properly at higher ratios.

There are a number of places where auxiliary air may be taken in. At Fig. 1 is presented a sketch of a motor with arrows indicating points where auxiliary air may exist and in addition to those depicted the valve guide stems may be offenders. Worn valve stem guides are noticeable in old motors and frequently are the cause of the difficulty experienced in adjusting the carburetor for an all-around mixture.

With auxiliary air the low speed must be enriched to prevent missing, but usually too much gas is then present on the high speed, which results in heating. The spark plug and priming cup fits may be tested with oil and if any leaks exist bubbles will be given off. A better method is to employ soap suds, especially if the leak be a small one. The intake members may be tested by using gasoline and noting the action of the suspected cylinders when extra fuel is led to them.

Disassembling Differential.

(55)—Am planning to overhaul my machine, which was a pleasure car. I do not understand how to proceed with the differential. The axle is of the full floating type. Any suggestions, with illustrations, will be appreciated. I would state that I cannot obtain an instruction book and wish to do the work myself.
MOTOR TRUCK READER.

Fitchburg, Mass., Dec. 24.

The method of disassembling the differential is shown at Fig. 2, the steps being arranged in alphabetical order. With the full floating type axle it is not necessary to jack up the wheels, as the driving shafts or axles may be displaced with the wheels on the ground.

The housing plates A and B are first removed, which will expose the differential. If the driving gear C is to be taken out the slip joint member will have to be displaced. The retaining clamps D are held by bolts and by taking these out the differential as a unit may be lifted out of the housing P. The differential E then may be placed on the work bench for disassembling.

It will not be necessary to remove the large gear unless repairs are required. It is secured to the housing shown at F by bolts, and it will be noted that these are wired to prevent their becoming loose. The housing F is in two sections, each containing a gear as shown at G and K, four bolts holding the two parts together. The two gears with the spider and its small gears may be displaced as a unit as indicated at N. The spider assembly is depicted at O. The reassembly is made by reversing the order outlined.

After doing the needed work, be careful to set up all nuts and bolts snugly. Lubricate the bearings and small gears with oil and pack the entire assembly with grease. It is advisable to test the differential in the housing for lost motion—side play—and if any exist take up on the bearings, if of the adjustable type. In

Fig. 2—Illustrating the Steps Taken in Disassembling Differential of Full Floating Type of Axle.

this work care must be taken to rotate the adjusting member the same number of turns on each side. It should not be too tight and ought to rotate freely.

TRUCK FREIGHTAGE FASTER THAN TRAIN.

Single Machine Carries Six Tons Each Way Nightly Between Boston and Providence, Saving Time of Men and Equipment for Company and Better Serving the Public.

OPERATING its principal service between Providence and Boston, the Boston, Providence & Fall River Express Company carries the bulk of its freight between these cities by motor truck, competing with the railroad and large express companies, and making deliveries in quicker time and at less cost. This is not an experiment, for it has been operated since March, 1913, and experience has shown that the company can afford its patrons service that cannot be equalled by other concerns. Up to the time truck transportation was begun the company had shipped its freight by railroad. The management, with the desire to promote and develop patronage, had made every endeavor to expedite shipments, collections and deliveries, and the possibilities of quicker transportation, with arrivals and departures that would better serve its customers, led to the use of the machines.

The company was established a number of years ago with a service that consisted of horse and wagon at Providence and a similar outfit at Boston. Packages were collected and delivered in either city, shipments being made by fast freight trains that were supposed to leave each evening early in the evening, arriving in time for delivery the next morning of the following day. The distance between the geographical centers of the two cities is 45 miles, and the purpose of the road was, and now is, to

haul the fast freight cars through during the night, bringing all receipts up to 6 in the evening, that these could be ready for delivery to the consignees the morning of the next day. Regular freight might be in transit two or three days to a week in transit, but to meet the demands of business men the special fast service was inaugurated.

Special Delivery Service.

From its inception the company's business was devoted to serve those who did not maintain vehicle equipment, giving to its customers quicker, and cheaper, service than that afforded by the large express companies, or, in other words, making special delivery instead of general distribution, and with the use of giving an attention that could not be expected from other concerns engaged in similar, but diversified, transportation. The railroad had as its purpose the shipment of the freight accumulated

during the day, sending it all at one time, this economizing cars, clerical work, and general expense, the belief being that this would work out to better results than were shipments made more frequently and in less volume, leaving to the express companies the transportation of the packages urgently required.

This condition does not differ materially from that in other localities so far as freight transportation is concerned, the interests of the large express companies, which are largely owned by railroad corporations, being conserved so far as possible by the contracts and traffic agreements entered into by them, although nominally having separate existence. So long as the public is dependent upon railways for the haulage of freight the business interests of any community must be largely, if not wholly, subordinated to the fa-

The Five-Ton Peerless Truck That is Driven a Round Trip Between Providence and Boston Six Days a Week, Carrying a Full Load of Freight, for the Boston, Providence & Fall River Express Company.

cilities of these corporations, and service is generally based on volume carried. The people have the choice of which will best serve them. The freight is usually hauled at either end of a shipment by other interests, but the express companies usually collect and deliver, although shipments may be made between points without this service. But the rates are based on collection and delivery, unless the business transacted at any given point is so small that no vehicle equipment is maintained there.

Changes of a Decade.

Considering the freight and express business between Boston and Providence, a careful analysis fails to show that any progress has been made in a decade, so far as expediting shipments and minimizing expense is concerned. Additional freight cars have been sufficient to meet the requirements of excess shipments without extra trains, and the express companies

have met all demands upon them in much the same manner. The increase of volume has been provided for without giving the business men faster service, and the expense is greater, there being no decrease in prices as a rule, or no change until the parcel post rates compelled reduction with reference to packages of small size.

Probably this is one of the principal reasons why the Boston, Providence & Fall River company has steadily developed in proportions. With a view of increasing its patronage the company established agencies in Fall River, New Bedford, Pawtucket, Woonsocket, Attleboro, North Attleboro and Taunton, having direct representation in these towns and cities, and later became affiliated with the Bay State Street Railway Company, which maintains a freight and express service, in connection with which it represents that company in Providence, and has contract with the Rhode Island Company to transport its business between Providence and Fall River. In addition the company maintains an express service between Providence and New York by steamer.

Developing the Business.

The development of the business is extremely interesting, largely from the fact that the company forwarded and received its freight by the railroad, but by specialized handling received it later and delivered it earlier, this service creating patronage and attracting business men who found it especially desirable to them. As a matter of fact this condition may be found in nearly every community of such size that highway transportation equipment is necessary, and where trade is even in moderate volume.

The average express business of today is systematized much as is the postoffice department, so far as shipment and delivery is concerned. Special express trains are operated where the volume of business is sufficient and from large commercial centres through cars are loaded that are either completely made up and sent to distant points, or receive packages at stated points. In other instances the cars are included in passenger trains and are delivered at the destinations at regular times. But no matter when received deliveries are made by routes, and these are served at stated intervals, once or more daily. The frequency of delivery depends entirely upon the volume of freight and the proportions of the city or town.

Question of Rates.

The Boston, Providence & Fall River Express Company had to use the fast freight of the New Haven railroad, and at its terminals horses and wagons were used for collection and delivery, these being the same facilities as were used in the service of the large express companies. But instead of route deliveries and the consequent delays, special distribution was expected to be of such material advantage to the business man as to impel his attention. But an additional inducement was the rate for transportation, which was fixed as 75 per cent. of the express companies' prices, but 50 per cent. more than railroad freight charges.

One reason for establishing the intermediate rate between the fast freight and express prices, was the necessity of attracting a sufficient volume of patronage to insure a reasonable business. The specialized service seemingly offered advantages to justify charges equal to those of the express companies, considering the substantial saving of time, but in addition to this there would appear to be every reason for business men to support a company that could afford them protection through its competition with the railroads and express companies. Experience has been that promotion of patronage for competing concerns is beneficial to the people as a whole.

Utilizing Motor Trucks.

Not until motor trucks became well recognized as practical utilities did Manager W. S. Brown consider the possibilities of using them between Boston and Providence for the haulage of freight. He was doubtful as to results in so long a haul, but after making careful investigation made contract with the owner of two trucks to have the freight carried overland between Providence and Boston, two trips to be made daily, leaving Boston at noon and at 7 in the evening, carrying the loads through from one receiving station to the other without stop. The intention was to use the trucks for the freight sent by railroad, but shipping twice daily instead of once, and making possible the delivery in Providence of packages received up to the time of departure from Boston at noon before the close of the business day.

Service Begun with Two Peerless Machines.

The service was begun in March, with two Peerless trucks, one of three tons and the other four tons capacity, and the schedule arranged was for four hours' running time. As planned the truck leaving Boston at noon would be in Providence by 4. This truck was loaded at Providence as soon as practicable and sent back over the road, leaving not later than 7 in the evening, and reaching Boston about 11. The truck leaving Boston at 7 in the evening reached Providence about 11 at night, unloaded and again loaded, so that it could be sent off by 1, that it would be in Boston early in the morning with the second load.

The reader will understand that this service was intended to directly benefit the business men of Providence. The company operated eight single-horse wagons in Providence and a similar number in Boston, for collection and delivery. The Adams Express Company received packages early in the day at either its Boston or Providence offices and delivered them in either city in the afternoon, but unless received by 9:30 distribution could not be depended on. With the use of the truck packages could be received in Boston up to 12 and delivered the same afternoon at a saving of 33 per cent., this ratio of saving being based on the lowest price established for the work.

Transportation Costs.

In connection with rates, the value of collection and delivery must be considered, and as an illustra-

It may be stated that a large Providence shipper, who has figured costs of transportation very carefully, has found that it is more economical to send packages weighing 250 pounds or less by express, for the price paid includes handling, hauling and transporting, and eliminates the expense of maintaining equipment and men to do this work. But when packages weigh more than 250 pounds the difference in rates is such that they can be sent cheaper by freight. This is based on general conditions and the supposition that there is sufficient work for men, animals and vehicles, and it does not take into consideration the value of the quicker transportation.

The freight rate between Boston and Providence is 100 cents a 100 pounds, for packages of that weight or more, but smaller packages are carried at considerably higher rates. The express rate is 40 cents a 100 pounds, with the charges graduated for smaller units, while the charge made by the overland company is 30 cents a 100 pounds. The most profitable business is in smaller packages, but there is reason for the great ratio of price, as there is precisely the same clerical work to be done with a bundle weighing one pound as with one of 250 pounds, and perhaps a dozen handlings, as many deliveries, and the time of a man, horse and wagon for possibly a considerably longer period, so that comparisons by weight alone cannot be justly made. This statement is made for the purpose of showing that with a rate of 30 cents a 100 pounds a large number of packages might earn for the company an average of 40 cents or perhaps more.

Saving in Time.

The truck service was found to be a distinct saving in time, which is a decided benefit for the consignees. To illustrate: A shipment of a car from Boston at 7 o'clock meant that the last package could not be received later than 6, and after the records had been made up and the freight delivered to the receiving station of the road the train was dispatched as soon as made up. On arrival at Providence the car was placed in the freight shed and in the morning delivered to the freight office, unloaded, the records made, the packages sorted and delivered to the teamers, then delivered to the company, redistributed and sent out by wagon, as routine was followed at Boston. But in the event of delays in handling the cars in the freight sheds, in unloading the freight, in making the records, and in the customary congestion of vehicles in the streets and at the freight houses, hours may be lost. Before the trucks were used the drivers, horses and wagons were kept waiting at the office or at the freight house until the shipment of the night before was ready for distribution, and not infrequently the wagons could not be started out until 9:30 or later at Providence, while at Boston under favorable conditions freight could not be distributed until 9:30 and from that time until 11, or even noon. This was not peculiar to the business of this company, for practically all shippers have like experience. The loss of time and the increased expense entailed, to say nothing of the dis-

satisfaction of business men, was the reason that prompted the use of the machines.

To facilitate the business, when the trucks were placed in service the records were made up, for a waybill is made out in regular form, as the packages were received, and with a truck waiting at the office freight could be taken up to the time of leaving. This insured making every call and serving every customer up to the close of business. At the Providence office a man was placed on night duty who prepared the waybill and made up the records of every package received up to the end of the business day. On the arrival of the truck at 11 the freight was unloaded, the record written and as quickly as practicable the machine was loaded and sent back. In the Providence office the local delivery sheets were written, the freight sorted for routes, and it was in readiness for loading when the drivers arrived with their wagons in the morning. As might be assumed, this meant an extremely early delivery, and by 7:30 the drivers and their wagons were on their routes, and with a saving of from two to three hours that had previously been occupied with waiting and handling of freight. With all of the preliminary work disposed of by the night man, attention could be devoted to the early shipments by other lines that came through the freight houses and by steamer. With the reduction of the Boston shipment the volume of business to be handled immediately was relatively small, and this meant opportunity for doing more work with the same equipment and the development of patronage.

At Boston, the arrival of the truck load of freight at 5:30 or earlier made it possible to have this unloaded, written up, sorted and ready for distribution by 7:30, and this was a big relief as compared with the conditions previously existing, the results being similar to those obtaining in Providence. Both at Providence and at Boston the packages received up to the time of departure were made in readiness, and in the latter city the truck was brought to the terminal and loaded, freight being taken up to the minute of departure.

Endurance of Machines.

The systematization of the work required comparatively little time and from the first day the gain was large and the service so satisfactory that there was no doubt of the success of the plan, but the one matter of doubt was the endurance of the machines under so long a run at capacity loads. One round trip for each truck was more than 90 miles a day, and this was for six days a week. This would mean about 550 miles weekly, or a total of close to 28,000 miles a year, unless the machine was withdrawn from service. This appeared to be a very large mileage, carrying the loads required to be profitable, and the doubt was whether the machines would endure as long as was estimated.

Careful estimate of the cost had been made by the contractor, he being guided by the advice of other men engaged in truck transportation, and with this as a

standard, record was kept to determine whether or not the trucks were economical. The contractor was paid a flat price for a trip, and the load was large or small, just as conditions developed, for departures and arrivals were necessarily on schedule. Experience showed, however, that the three-ton Peerless machine was too small for the work, as the character of the load, generally bulky, and the long haul, made necessary the carrying of larger freights than could be handled with this vehicle. By this is meant that to be operated at a satisfactory profit at the rates charged a load of five or six tons should be carried. The cost of operating a six-ton truck is comparatively little more than a machine of half that capacity, and with a six-ton load the earnings would be sufficient to justify the use when contrasted with other forms of transportation, but the earning power of a three-ton truck would not be sufficiently in excess of the operating cost to warrant its use in work of this kind.

Larger Equipment Needed.

After an experience of three months the contractor decided that he could not continue with the equipment he had, for larger loads were necessary for him to make a sufficient profit on his investment. Accordingly the contract was terminated and the company purchased the large machine and sent it to the Peerless branch at Boston, where it was rebuilt to the extent of replacing the springs, axles, wheels and tires with parts the same size as those used for six-ton trucks, and it was then placed in service, leaving Boston each day at 7. Since July the truck has been driven over the road each day, carrying a load up to six tons, and making the round trip of 90 miles or more with but one delay, when the machine was held in Providence by the driver. As a matter of fact he might have gone through with the truck, but he was over-cautious.

The truck is operated on the schedule stated for the departure at 7. It is loaded at Boston late in the day and started promptly on time. The run through to Providence is made in from three and a half to four hours, and usually it is in before 11. The load is taken off and it is reloaded, leaving for Boston between 12 and 1, and reaching there usually by 5 or 5:30. There the freight is taken to the receiving station, where by 7:30 the load is ready for distribution by the wagons. The truck is sent to the stable, where it is kept until perhaps 4:30 or 5, when it is sent to 65 Pearl street and again loaded for the Providence trip. Four afternoons of the week, however, the truck is used for hauling freight from the railroad yards, and this considerably increases the weekly mileage.

Saturdays the truck leaves Boston according to the schedule and goes back from Providence with the load accumulated during the day, reaching Boston early Sunday mornings. No trip is made Sundays, and this arrangement allows the 36 hours between Sunday mornings and Monday nights for whatever attention may be necessary. With the work required of this machine the necessity of systematic care is

realized, and while the driver is expected to make adjustments and minor repairs, any work of consequence is done at the branches of the Peerless company. This insures the machine being in good operating condition at all times.

The machine has a body that will permit the carrying of a freight of large bulk, and it is often sent out with a load piled so high that it will just clear the trolley wires in the streets. The use of a standing top with loads of such size is not practical, so the freight is covered with tarpaulins, that afford ample protection, and the driver is sheltered by the cab.

Value of the Service.

When the day's freight is in excess of the capacity of the truck the surplus is sent by railroad, and the experience with this is practical evidence of the superiority of the machine for this character of work. The saving in time and the benefit to the business men is a very large factor with the company, and this has been obtained by the use of the truck. Recently the machine was off a few days for an overhaul and during this time the freight was sent by train. The difference in the service was so pronounced that every customer of the company was anxiously inquiring when the machine would be ready for operation. Probably no better demonstration of the actual value of the truck service could have been made to them, and they realize now very keenly the advantages they have in the overland express.

Manager Brown states that the cost of operating the truck for freight purposes is more than was estimated before the practical experience with the machines, and the expense for transportation may be said to approximate that of railroad haulage, but being largely independent and in a position to arrange its service to meet the requirements of the business men, and to make deliveries early each business day, are extremely important factors in influencing patronage. Besides this, there is the extremely moderate rate. The intention of the company is, early the coming spring, to add another truck to the Boston-Providence service, and this will leave Boston at noon and give Providence the same late afternoon delivery it had when the two trucks were operated.

Fall River and New York.

There are, of course, conditions when overload freight and express haulage would not be as productive, as between Providence and Fall River, for four shipments are made daily by electric express, and the collections and deliveries are made by this company. The distance between points is 22 miles, and there is no steam road service. The cars are dispatched on practically passenger schedule, are handled quickly, because there is no congestion at the freight houses, and the freights can be sent out for delivery with comparatively little delay. This demonstrates the possibilities of the railroad that can make car or partial car shipments as against the road that must operate its cars in trains and, so far as possible, fully loaded.

The company's express business between New

and Providence is carried by steamer, and this facilitates final collections in season for the sailing of 1913, which is a handicap in competition with the other companies that can make collections as late as 9 o'clock in the evening in New York and have the packages in readiness for delivery in the morning. In Providence, however, the collections can be made to the close of business hours. There is an advantage in the fact that the delivery is specialized, made of by routes, and at both ends the deliveries are generally earlier. The difference in the rates, however, and the fact that a great deal of the business is in New York, to a considerable extent offsets the advantages of later collections in that city for east end business.

The highway between Boston and Providence is in good condition, the greater part of the surfacing being gravel or oiled, and the grades as a rule are not steep, although there are several long hills. The route is through Pawtucket, North Attleboro, Plainfield, Wrentham, Walpole, Norwood, Westwood and Attleboro, following the highway that is Washington Street from the Rhode Island line to the Charles river in Boston. When the line was established the purpose was to give each of these towns an express service to Boston or Providence, but the business at either end was so large that this was for the time being abandoned. With the installation of another truck it is probable that deliveries and collections will be made on a regular trip, which will add materially to the volume of business and better serve the business interests at the terminals and along the route. The Peerless truck will go through the winter, and a new machine will take its place while it is being overhauled, and then it will be used regularly. That is the plan unless a change is made.

NON-GRAN BEARING METAL.

Non-Gran bearing metal, manufactured by the American Bronze Company, Berwyn, Penn., is claimed by the manufacturer to have unusual qualities in that the structure of the metal is fibrous instead of granular and for this reason extremely enduring while under frictional stress. The metal has been developed with extreme care for the use specially made of it, and this is made of the necessity of having bearings that will endure, for without these motor efficiency is impossible to secure and constant expense is entailed in repairs. The maker maintains that the metal is especially desirable for use with motor service wagons because of its long endurance and comparative economy.

The Steel King Motor Company has been incorporated in Detroit by Jerome Remick, Samuel Mulford, Stair, W. T. Barbour, Charles A. Dean, A. A. Metz and J. F. Nagle to manufacture tractors and traction plows. A factory is to be established at Lieber streets in Detroit.

GMC PRICES REDUCED.

Abandons Unlimited Maintenance, Free Service and Trading for Old Trucks.

The General Motors Truck Company, Pontiac, Mich., inaugurated Jan. 1 a new policy that includes a very substantial reduction in prices of both gasoline and electric wagons and trucks, the elimination of free maintenance service, sales for time payments and receiving old machines in partial payment for new vehicles. But the guarantee against defective material or faulty workmanship is continued as before. The statement is made that the GMC machines will be sold at the lowest cost that is consistent with high class products. This reduction is very generally applied to the entire list of machines built, and while the maximum is \$1500 for a five-ton gasoline truck and the decrease will be from 33 to 22 per cent., with this line, the electric vehicles will be sold from \$185 to \$675 less than before.

Vice President and General Manager W. L. Day states that when motor trucks were more or less experimental they required close supervision by the manufacturer, which developed "free" service, which necessarily entered into the price fixed by the builder. In addition to this unlimited maintenance agreements placed a premium on neglect and abuse and created a very costly burden for the manufacturer. The conditions caused high prices and to offset these time payments were accepted by some and prices were indirectly reduced by excessively large allowances for used machines. These factors are believed to be materially responsible for the price scale of motor wagons. The company has realized the effect of these influences and in establishing its new policy believes that the expansion of the market and the increased volume of factory production will justify the sale of machines at much lower prices, the distinct beneficiary being the purchaser. The buyers will undoubtedly assume a new responsibility toward their investments, and this will eliminate the need of favors of the manufacturer, regarded as gratuitous, but necessarily considered in the market price.

The Heinze Electric Company has established a sales office and service station at 1876 Broadway, New York City, which is in charge of P. G. Sedley, where a full stock of ignition specialties will be maintained.

The campaign for funds for the construction of the Lincoln National Highway is being actively waged, and contributions are constantly being received at the headquarters of the association in Detroit.

E. M. Lamb has been transferred from the management of the service department of the Gramm Motor Truck Company at Lima, O., to the Gramm Canadian Company at Walkerville, Canada.

TRUCK AN ECONOMY IN SHORT HAULS.

Large Crew for Machine and Quick Loading and Unloading Develop Satisfactory Results in Extended Experience of a Woonsocket, R. I., Haulage Contractor.

TO WHAT extent the people of any community are dependent upon transportation facilities is seldom realized by them. A very small proportion of the residents of town or city may have some knowledge of conditions, but the majority are blissfully ignorant of facts that would cause decided uneasiness were they known. This is particularly true of inland manufacturing communities, where the food, fuel, raw material used by the industries, building materials, supplies of all kinds, etc., must be received by railroad, and from railroad terminals distributed and redistributed. All shipments sent out must be made by the same lines. Obviously, the cost of transportation by rail and road vehicle must be paid by the people, and the handling alone becomes a considerable item. As this expense is regulated by the profit of those engaged in transporting competition is essential that it

handling the shipments and receipts would be ideal, but this condition is not often realized by the people. In few instances has this need been anticipated and provided for. Frequently the possibilities for economy have been ignored.

Freight Yard Facilities.

Until Jan. 1, 1914, the freight sent from and received at Woonsocket, R. I., a community of nearly 50,000 people, over the New Haven road, which monopolizes all railroad haulage to that city, was handled at six different yards scattered about the city, and beginning the first of the year it has been concentrated in a new yard. This is no doubt economical from the viewpoint of the railroad, but as all freight of less than carloads, and all carloads when there is no spur track on the property of the receiver, must be received there, the industries and commercial enterprises must haul such receipts to the shops, mills, factories, stores and warehouses.

This has revolutionized the haulage conditions and has increased the cost materially. Those who are engaged in vehicle transportation have found the need of additional equipment to handle the same volume of business, and as yet there is a good deal of uncertainty as to what will be required to do the work. There will be an advantage in having the shipments received at one point, which will eliminate searching for cars in different freight yards, the necessity of carrying partial

loads at times, and working in congested conditions, but the hauls will be much longer as an average. Coal, building material of all kinds, raw material for the manufactories, and the like, will be received in the freight yard, and the facilities for handling these must be provided by the transportation companies.

The Woonsocket Teaming Company.

The Woonsocket Teaming Company, owned by A. J. Sutton, is one of the largest contractors for highway haulage in the city, and is now using about 50 horses. While work may be said to be general in character, a great deal of it is for mills, for these plants do not maintain transportation equipment. Fuel, raw material and supplies are delivered to the mills and manufactured products taken from them. During the spring, summer and autumn a good deal of hauling is done for builders and those engaged in con-

Main 3.5-Ton Truck Utilised for Short Hauls Between Railroad Terminals and Mills by the Woonsocket, R. I., Teaming Company.

be kept at what may be regarded as a reasonable standard.

Railroad rates are usually governed by competition or by the approval of the Interstate Commerce Commission in the event of monopoly of the service. Rates within a state, however, are not subject to the regulation of the federal authority. Because of this fact state and interstate transportation charges may differ considerably, the shorter hauls generally costing more in proportion. Highway transportation is usually regulated by those engaging in it.

Vehicle haulage is from some recognized centre. It may be one or several freight yards, or from these receiving points and from piers or docks in the event of there being water lines. From these centres distribution radiates according to the needs of business. Concentration of terminals and adequate facilities for

struction. Household property is often moved and incidental service is given.

Anticipating the changed conditions, Mr. Sutton purchased a 3.5-ton Mais truck late in the summer and began experiment to determine just how it could be worked to good advantage, keeping careful record of the work done and making comparison of the expense with cost of animal haulage. Mr. Sutton has for a number of years had record of the work done for different concerns, and this was found to have a material value in determination of the economy of the motor truck. Because of the widely differing work and the fact that it was not possible to keep the machine constantly engaged in one class of service, the record covered a great deal of detail that was seemingly fragmentary, but it was found to be of decided worth in developing methods that make for economy.

Some of the mills receive bales of cotton and wool, and in hauling these, though the distance was comparatively short, the experience was that it would be practical to have a crew of three or four men and by quick loading and unloading to do the work comparatively cheaper than with horses, because the machine could make fast trips and could carry capacity loads. The same experience resulted with the haulage of cases and large packages, and as the greatest loss of time was in freight yards, decision was made to have a foreman, checker and several men at the new freight yard, who would collect the loads and have them ready for hauling as fast as the vehicles were ready to receive them. By this method quick loading was insured and with a sufficient crew on the truck to unload quickly the lost time was minimized. As to the driving, the expectation is that the truck will go between points as fast as conditions will permit, and the loads will be as large as can be carried consistently.

Handling of Goods.

The methods that obtained with horses before the change of conditions would mean a large proportion of lost time, because finding cars and moving freight could not be otherwise than slow work, and generally the crews were small. In anticipating the need of economy of time it was essential to ascertain the possibilities with the machines, and this could only be done by practical experiments to learn where the changes could be made, and after comparison of cost to modify the methods and by careful supervision determine the efficiency of these. In this manner it was possible to develop what is known will be productive of good results, and to improve upon these will be practical with greater experience and more careful systemization.

The handling of baled goods and packages with trucks is certain enough to be economical, but what can be done with coal has yet to be learned. The coal brought into the freight yard in cars and thus far it is shovelled into the carts. Experiment is to be made with loading machines that can be placed in the cars and operated with electric motors. The railroad has

made as yet no provision for discharging the cars by gravity and the loads cannot be left beside the tracks, so the contractors must necessarily develop such methods as will best serve them until such time as the changes are made that will permit of a greater measure of economy. The contractors using horses have no particular need for economizing time, but when trucks are in service every minute counts, and the material saving must be made in handling.

Mr. Sutton has just received his second Mais 3.5-ton truck, and three more are to be delivered to him early in the spring. He purposes to utilize these in general work, and the experience he gained with the first machine will be of material advantage to him. He believes that the economy is sufficient to justify the use of trucks in a large part of his business, although he will not dispose of all of his horses. Where operating cost shows economy of motor or animal vehicles that which is most productive will be used.

The value of the experience stated is that practical common sense methods were employed to determine how a condition could be met, and results obtained from experimental service will go a long way toward realizing the fullest utility of motor trucks. Material changes were necessary, but adaptations were made that were productive, and others will be adapted if occasion requires. The motor vehicle is regarded as least profitable in the short haul, but quick handling of freight is the solution of the problem. In work that requires longer hauls, however, there is quite as much need of expedition.

A remarkable saving was made by a contractor in an eastern city who has a six-ton Garford machine in his service. A recent work was the cartage of material weighing 2302 tons a distance of 3997 miles at a cost of 5.4 cents a mile for fuel and oil. This is claimed to be 25 per cent. less than the cost of feeding a sufficient number of horses to do this work.

A dividend of 1.5 per cent. on common stock, two per cent. on first preferred stock and 1.5 per cent. on second preferred stock has been declared by the United States Rubber Company, payable Jan. 31 to stockholders of record Jan. 15.

Proposal has been made to the stockholders of the Cass Motor Truck Company, Port Huron, Mich., to reorganize that concern, taking over the property and assets and considerably increasing its productiveness.

The Klingsmith Electric Truck Company has been organized by J. M. Klingsmith, M. F. Cure and E. F. Tiller of Chicago, Ill., with capital of \$350,000, to manufacture electric wagons and trucks.

The factory of the Singer Manufacturing Company, South Bend, Ind., has been bought by the South Bend Motor Works, and it will be utilized for the production of trucks and fire apparatus.

THE CONTINENTAL MODEL N ENGINE.

THE Continental Motor Manufacturing Company, Detroit, has begun the commercial production of a motor known as model N, which is the smallest engine ever built by that concern. The motor is intended for use in vehicles where light weight of power plant and moderate capacity will serve to meet all requirements. This creation is in line with the general purpose of designers to gain power by the combination of small bore and comparatively long stroke, and to secure economy of fuel consumption, these being essentials with the light machine that can be operated at minimum expense and yet have sufficient speed for all normal purposes. There is undoubtedly a demand for machines of reasonable power for service, and there is even greater need of economical operation, for engineering progression requires endurance and workmanship that will be the equal, if not the superior, of motors used for pleasure vehicles.

The model N engine is typical of Continental design and construction, it being a four-cylinder, water-

oil pan. This pan may be quickly removed, leaving the main and connecting rod bearings exposed. The use of pressed steel also eliminates the possibility of core sand working out and being carried with the lubricant to moving parts, which is a possible source of danger unless extreme care is taken. The crankcase is designed to use any standard magneto and several of the well known engine starters and lighting systems, the flywheel periphery being cut with teeth half the width of the face to mesh with the pinion of the motor starter shaft. The motor starter bracket is at the left side and a cover plate is fitted in the flywheel housing over the opening for the shaft and pinion of the starter if this equipment is not installed.

The crankshaft is of high grade material, carefully finished, with front, centre and rear main bearings 2.1875, 2.21876 and 2.25 inches diameter, respectively, and with length of 2.2875, 2.5 and three inches, in the order given, this making a total of 9.375 inches bearing length. The main bearings are babbitt metal in bronze

The Smallest Continental Motor: At Left, the Intake Side; at Centre, the Timing Gears; at Right, the Exhaust Side.

cooled, L head type with cylinder bore of 3.5 inches and stroke of five inches, the cylinders being cast en bloc. The water spaces are large and the block is cast with the head open, this being covered with a plate retained by cap screws. In the centre of the plate is the outlet manifold. The valves are at the right side, the operating mechanism being contained in pockets that are enclosed by plates retained by pairs of wing nuts. The cylinder block and the pistons are very carefully finished.

The upper portion of the crankcase is a casting of aluminum alloy and it is designed with a housing that extends over the flywheel, covering the upper half when engine and clutch are separate. When a unit power plant is required a lower half is provided, the remainder of the housing being bolted to the section over the flywheel. The arms that support the rear of the plant are cast integral with the housing, but the forward support may be an extension of the starting crank housing or lugs cast at either side at the front end. A material saving in weight and a considerable gain in strength is made by the use of a pressed steel

cages. The flywheel is bolted on to a flange forged integral with the crankshaft. The pistons and connecting rods have been designed with a view of reducing weight without sacrificing strength, and a considerable reduction has been made. The pistons are four inches length with walls .09375 inch thickness. The ribs found necessary in longer pistons to reinforce the heads are not required with those used in these motors. Three piston rings, each .09375 inch face, are used. The connecting rods are I section, drop forged from 35 to 45 point carbon steel, and heat treated. These are bored and reamed on special machines to insure the correctness of the centres and perfect alignment. The wristpins are chrome nickel steel, hardened and ground. The big end bearings are 1.875 inches diameter and 2.0975 inches length, of a fine quality of babbitt metal. The bearings are fitted with steel shims by which practically any adjustment may be made. The wristpin ends are bushed with phosphor bronze, 1.09375 inches diameter and 1.5 inches length.

The camshaft is large, having a forward bearing 2.625 inches diameter and 1.4375 inches length, and

bearing 1.5 inches diameter and 1.75 inches length. Inlet and exhaust valves are interchangeable and 1.0625 inches diameter, with nickel steel heads electrically welded to carbon steel stems. Both seats and stems are accurately ground to size and the stem ends hardened to minimize wear from the tappets. The usual means of adjustment for wear are found in the tappets.

As the efficiency of the motor is largely dependent on the **accuracy of the valve timing**, a great deal of attention has been devoted by the Continental engineers to this detail, and the model N valves are timed as follows: Intake, opens 17 degrees 53 minutes late, remains open 192 degrees 32 minutes, closing 29 degrees 25 minutes late; exhaust, opens 42 degrees 36 minutes early, remaining open 230 degrees 56 minutes, closing eight degrees 20 minutes late. The firing order of the cylinders is 1, 3, 4, 2.

The timing gears are helical cut and are practically noiseless in operation. They are housed in a case fully designed for effective lubrication. The motor is lubricated by the well known Continental system—a combination of splash and force feed. The oil is led to the reservoir through an outside filler and filtration is carried to the timing gears, where the flow drains to the pits in the engine base and where it is distributed by splash to the internal moving parts. The volume of oil in the reservoir is shown 1 time by a float operated gauge. The motor is cooled by a thermo-syphon circulation of water through the large cylinder jackets, the radiator, and by being mounted on an adjustable bracket carried on the forward end of the block, driven by belt from a pulley on the forward extension of the magneto shaft.

Though no announcement has as yet been made by the company concerning this engine, a great deal of interest has been aroused by some knowledge that it exists, and this has been productive of innumerable inquiries.

The Electric Storage Battery Company, Philadelphia, Penn., has issued catalogue section "SL", which is descriptive of the type X Exide battery for automobile starting and lighting purposes. This battery is designed to meet the service stated and has unlimited capacity for the weight and volume and construction that insures a clean and dry assembly. Each is a separate sealed unit, and the batteries are made up of three, six, eight and nine cells, affording 2, 16 and 18 volts, and batteries of 12 or more can be furnished in different sizes and assemblies.

The Postal Transfer Service Company, which has been in operation for transportation of mail in New York City, 42nd street south, has established its garage at 42nd avenue and 42nd street. It is a brick building, 100 by 200 feet, with the roof available for storage. The company has about 100 trucks and vans in use, these being divided into day and night runs about equal in numbers.

PATENT NOT INFRINGED.

J. S. Bretz Company Successful in Defense of Suit by Hess-Bright Company.

The suit of the Hess-Bright Manufacturing Company and the Deutsche Waffen und Munitions Fabriken of Germany, against Hedwig Fichtel and Ernst Sachs, engaged in business as Fichtel & Sachs, and the J. S. Bretz Company of New York, begun in 1911, has been decided by Judge McPherson of the United States district court for the eastern district of Pennsylvania, sitting at Philadelphia, and is in effect that the defendants do not infringe upon the rights of the complainants, and a decree was entered dismissing the bill at the cost of the plaintiffs.

The Bretz company is American sales agent for Fichtel & Sachs, and the complaint was founded on alleged infringement of the Conrad patents, so-called, which cover a continuous and uninterrupted race construction of a ball bearing. The Conrad patent is owned by the Deutsche Waffen und Munitions Fabriken, the Hess-Bright Company being its American agent. The decision limits the Conrad patent to a bearing of any kind having no notches inside of either ring for the introduction of the balls, and to a bearing having a limited number of balls, being only such number as may be inserted in the crescent shape formed by eccentrically displacing the rings, and having separators between the balls.

This decision is regarded to be of material importance because numerous concerns, both in Europe and this country, manufacture ball bearings, and until this determination the complainants had successfully protected the rights insured by the Conrad patent. The concerns that are more or less affected by the decision are the M-B, R. I. V., S. K. F., S. R. O., Schaefer, H. C. B., Ideal and Rhineland, made by foreign companies, and the New Departure and the United States, made in America.

According to Alfred H. Bartsch, advertising manager of the Bosch Magneto Company, more than 1,000,000 magnetos are now in use in motor vehicle equipment in America, which statement can be accepted as reasonably conservative. When all other forms of gas engines are considered this total will probably be increased to 2,500,000. The enormous use of the internal combustion motor is not realized until facts of this character are known. Magnetos were not used for vehicle engine ignition to any material degree until 1908, and in six years the use of these instruments has become well nigh universal.

The New England branch of the Kissel Motor Car Company at Boston, Mass., has been placed under the management of Ralph Ketchum, formerly of the R. & L. Company of Boston, who has succeeded H. B. Pruden.

BOSTON'S TRUCK SHOW.

Numerous Applications for Space Already Insure Success of the Exhibit.

Plans are rapidly approaching completion for the third annual motor truck show to take place at Mechanics' building, Boston, Mass., March 17-21, and Manager Chester I. Campbell is very sanguine that the exhibition will be superior from every point of view to any yet held in that city. Boston will be the only large city of the country in which an exhibition of service vehicles will take place this year, and with the keen interest in motorized transportation equipment obtaining generally in New England the management is looking forward to large attendance and increased patronage.

This will be the only opportunity for manufacturers seeking representation in one of the best markets of the country to make exhibition, this form of introduction to prospective agents and the public having a distinct advantage as contrasted with campaigning by sales managers for those interested in agency propositions. This has attracted a considerable number whose vehicles will be seen for the first time, while many of the standard makes of machines of known reputation will be shown. Judging from the spaces engaged and the applications pending there is the best of reason to believe that the show will be the largest of the kind ever seen in Boston, and the number of makes and types of vehicles will no doubt be considerably in excess of any previous exhibition. In fact, it is believed that this show will make records of all kinds.

The use of motor wagons and trucks is increasing very rapidly in New England. The coming season is expected to be the best ever known from every point of view, and the show will undoubtedly attract thousands of interested visitors. Last year many business firms considering motor vehicle equipment had their engineers systematically examine the types of machines shown that were suited to requirements, and reports made resulted in a considerable number of sales. Comparisons of distinct value could not be made outside of an exhibition save at large expense. While the display of accessories will be secondary and will be naturally confined to what can be utilized with power wagons, this division will be of material interest and will include a considerable number of interesting exhibits.

Merchandise creditors of the Brown Commercial Car Company, Peru, Ind., now conducted by William B. McClintic as receiver, and against which bankruptcy proceedings were recently instituted, are desirous that Mr. McClintic be continued as trustee. These interests are favorable to any proposition that will permit the reorganization of the company or continuing it as a going concern.

VEHICLE OWNERS RESIST UNIONS.

Indianapolis Employers Unite for Defense Against Demands of Employees.

During the recent strike of street railway employees at Indianapolis, Ind., which was resultant from an endeavor to unionize the vehicle drivers of that city, the Employers' Association was instrumental in the formation of the Commercial Vehicle Protective Association by practically all the concerns of the city employing drivers. This organization raised funds, established headquarters, and an executive committee directed the activities, police authority being conferred on drivers who wished to work, while a force of 500 citizens, all armed and 100 of them mounted, supplemented the work of the police department.

Attention was then directed toward moving highway vehicles with the result that in four days conditions were practically normal, and the great majority of the firms were ready to operate with their regular drivers. The number of men who refused to work until the union had been recognized was comparatively small. There was but slight retardation of business and some firms suffered no loss through the delays incident to the strike. The strike has not been officially terminated, but the union members have been advised to seek employment, to make verbal agreement as to wages and to obtain permission to wear the union button, but recognition of the union is not sought for. Employers who are members of the Commercial Vehicle Protective Association are generally refusing employment to union men on the ground that they would agitate unionism among non-union employees.

The principal result of the strike, so far as the city is concerned, has been the unification of the business interests for protection against not only labor domination, but the general preservation of the rights of the people. The Employers' Association is being reorganized on broader lines, and endeavor will be made to maintain the "open shop" policy in all industries of the city.

The Los Angeles Brewing Company, Los Angeles, Cal., has purchased seven White machines, one of 3000 pounds, three of 6000 pounds and three of 10,000 pounds capacity. These are to be fitted with stake bodies and will be used for brewery service. When these shall be delivered the company's equipment will be completely motorized. The purchase was made after the company had made experiments with motor vehicles for several months.

George Uehlien, president of the Universal Motor Truck Company, Detroit, has purchased the interests of F. K. Parke in that corporation and Mr. Parke has retired as general manager and from participation in the activities of the concern.

"SILVER ANNIVERSARY" BOOK.

The Building of an Industry" is the title of a publication produced by the Electric Storage Battery Company, Philadelphia, Penn., for private distribution which deals with the history of the company from its inception in 1888, a period of 25 years. Beginning with the arrival of Clement Payen in this country in 1887, and following the acquisition of his interest by Philadelphians, the subsequent formation of the Electric Storage Battery Company in 1888 and the beginning of the manufacture of the "Chloride Accumulator" at Gloucester, N. J., the story is told in chronological form, the first describing "The History", the second "The Product", the third "The Factory" and the fourth "The Organization".

Beginning with five men the company has increased until it is one of the best known and one of the most substantial industries of the country, with a factory in Philadelphia that occupies 23 separate buildings and has 12.25 acres of space, and its branches, sales and representatives can be found in hundreds of cities. The development of the company industrially is intensely interesting, but it is paralleled by the adaptation of storage batteries to innumerable purposes. A description of the manufacture of cells is necessarily omitted, but some of the processes are outlined, and mention is made of the promotion of the welfare of the workers in the factory. The names of the officers, directors, department heads, engineers and sales men are included in "The Organization". The book is carefully designed, illustrated and printed, and each page is bordered with a heavy rule of silver, symbolical of silver anniversary of the company, and as a publication is exceptionally attractive. It is a decided treat to the publisher.

With a view of locating a branch factory representatives of the Continental Motor Truck Company Denver, Col., have examined sites at Waterloo, Ia., and several other cities.

The Akron Airless Tire Company has been organized at Akron, O., for the purpose of manufacturing a tire core that will be adapted for use with pneumatic shoes on service wagons.

Chicago capitalists propose to establish a motor bus service in Michigan and Jackson boulevards and Meridian road in that city.

WESTON-MOTT AXLE.

Full Floating Type for Use in Vehicles of Capacities to 2000 Pounds.

The Weston-Mott Company, Flint, Mich., is now producing a rear axle that is designed for use with either gasoline or electric vehicles and so constructed that the frictional losses are minimized. The axle is a full floating type and is thus far made in two sizes, which are designated as types 970-L-D and 990-L-D, the former for use on machines having 1500 pounds capacity and the latter for vehicles having 2000 pounds capacity. This axle is shaft driven and it is built with a reduction gear in combination with the differential so that it may be coupled to the main driving shaft and in this unit reductions of from 5:1 to 10:1 obtained, this being far greater than could be obtained with the single bevel gear without making the gear

The Full Floating Rear Axle, Adapted for Either Gasoline or Electric Machines, Made by the Weston-Mott Company, Flint, Mich.

of a size that would be impractical for use because of the extreme diameter of the axle housing and the very small road clearance, to say nothing of the materially increased cost of production and necessarily larger selling price.

The axle housing consists of a centre section with a cap that is practically the full diameter. This cap when removed exposes the entire back of the differential assembly. Into the arms of this housing the shaft housings are fitted, and the outer ends of these carry sleeves that support the spring seats and the brake flanges. The brake shaft brackets are mounted on the axle shaft housings. Forward of the differential assembly the housing is divided transversely and at this division is mounted the cross shaft of the reduction gear, and the forward section carries a pinion shaft that is supported by ball bearings, the forward being a double thrust bearing and the rear a single

bearing. The cross shaft carries at the right a bevel gear that meshes with the pinion of the pinion shaft, and a spur pinion that meshes with the spur gear of the differential, and this shaft is also mounted with a double ball thrust bearing at the right and a single ball bearing at the left. The differential assembly is installed on roller bearings.

The ends of the axle shafts are fitted with dog clutches fitted into the wheel flanges and the wheels are mounted on Timken roller bearings. The entire axle assembly is enclosed in an oil tight housing and its operation should be practically noiseless. The bearings have been selected with a view of affording maximum efficiency and endurance, and the materials have been determined with the purpose of securing maximum strength and minimum weight. The shafts and gears are made of an alloy steel that is carefully heat treated, and the axle housing is a special material that will endure under the use expected of a vehicle driven

BAKER FOUR-TON DUMPING TRUCK.

Standard Electric Chassis Equipped with Power Discharging Body.

A quick discharging body that can be operated by hand or motor has been designed for use with the standard four-ton truck chassis built by the Baker Motor Vehicle Company, Cleveland, O., and the equipment can be installed at the option of any purchaser. The body is constructed for endurance, having a frame of angle iron with sides and ends of steel plates, these members being riveted. The floor is built of steel channels securely riveted, these being covered with a steel plate that forms the floor. The tail gate is opened and closed by a lever mounted at the side of the seat of the driver.

The body can be elevated to an angle of 45 degrees,

and is hoisted by means of two arms secured to the sides of the body below the floor. These arms are actuated by a large steel cross shaft that is installed transverse of the chassis frame, and revolves in one direction only. Two-thirds of one revolution is required to elevate the body to its greatest height, and the other third revolution of the shaft will lower the body to its seat on the chassis frame. Naturally the body may be lowered in half the time required to raise it, the entire dumping operation requiring 50 seconds.

As will be noted from the accompanying illustration the body is hoisted by a shaft extending longitudinally of the chassis that carries a worm that

Four-Ton Baker Electric Truck Fitted with a Steel Body, with Either Hand or Power Hoisting Apparatus.

on solid tires. The axle is fitted with a truss rod to insure against sag. When used with an electric vehicle the motor shaft may be coupled with the pinion shaft, and when used with a gasoline machine the driving shaft may be coupled with the pinion shaft. The statement is made by the manufacturer that the construction is such that the axle may be used without radius rods, it having sufficient strength to endure the stresses of constant service under severe working conditions.

A quarterly dividend at the rate of seven per cent. annually was ordered by the Packard Motor Car Company, payable to all holders of preferred stock of record as of Dec. 3, on and after Dec. 15. This is the usual rate of dividends that has been paid by this company on its preferred stock during the last several years.

meshes with a worm wheel, which in turn drives a train of reduction gears that actuate the cross shaft. The shaft is amply lubricated, the bearings being in oil tight housings. The shaft may be driven by an auxiliary motor supplied with power from the battery, or it may be turned by hand.

The sizes of standard bodies for handling fuel and construction material are as follows: Coke, 11 and 14 feet length, four and six feet width, and three feet height; coal, 10 and 14 feet length, four and 4.5 feet width, 1.5 and two feet height; sand, 10 and 14 feet length, four feet width, one foot and 1.5 feet height, the last dimension including three-inch flareboards.

The New Departure Manufacturing Company, Bristol, Conn., maker of ball bearings and differing specialties used in motor vehicle construction and equipment, has added \$500,000 to its capital.

PHILADELPHIA SECTION, E. V. A. PROMOTING ELECTRIC HAULAGE.

Fourth Division of the Organization Formed in the Quaker City.

The fourth division or group of the Electric Vehicle Association of America was organized at Philadelphia, Dec. 15, this body being the development of the interest created in connection with the annual convention at Chicago last October. The preliminaries had been provided for and when these had been completed the formalities took place. The body will be known as the Philadelphia section, and it will have the same scope of the New York, Chicago and New England sections, conducting its own activities and participating in the general promotive work of the national association.

The following officers were elected: Chairman, R. L. Lloyd, Philadelphia Electric Company; vice chairman, A. W. Young, Public Service Corporation, Camden, N. J.; secretary and treasurer, J. C. Bartlett; directors, W. H. Johnson, Philadelphia Electric Company; E. P. Whitney, Commercial Truck Company of America; Frank B. Neely, Electric Storage Battery Company; James M. Skinner, Philadelphia Storage Battery Company; Carroll A. Haynes. Mr. Lloyd, by his election as chairman of the section, becomes the fourth vice president of the Electric Vehicle Association of America.

A KisselKar truck owned by the John Irwin Wholesale Grocery Company, Calgary, Alberta, has been used by that concern for a year, being operated through parts of two winters and in conditions that are unusually severe, because of the frequent thaws that transform the roads into rivers of deep mud, without the loss of a day's time. Another truck owned by the Great Western Liquor Company of the same city has been used nine months without repair and no road delay has been experienced.

The Bridgeport Auto Company, recently organized at Bridgeport, O., is to build a general line of vehicle, motor boat and aeroplane engines. A factory is shortly to be erected. The company may be merged with an eastern company now engaged in building vehicles.

A building 100 by 30 feet has been built by the Western Motors Company at Sacramento, Cal., work begun on another structure 100 by 200 feet. It is expected that several other units will be added to the plant, which will produce delivery wagons and trucks.

An ordinance introduced by Alderman W. C. ... requiring that all service wagons and trucks in that city be equipped with fenders, is pending before the city council of Milwaukee, Wis.

New England Section, E. V. A. of A., Starting Campaign in Bay State Cities.

The New England section of the Electric Vehicle Association of America has begun a campaign to generally stimulate the interest of the people generally in electric cars and service wagons, and to this end purposes to hold at different times public meetings in cities throughout New England. In this work the members of the section will endeavor to interest local trade organizations, and all will unite in general promotion, expecting, of course, that the central station company of the city or town will co-operate and follow up the campaign by such methods as appear to be promising.

The meetings of the section are usually held in Boston, the members coming from the towns and cities in New England and having the opportunity of listening to speakers of recognized ability, who are generally specialists in transportation efficiency. Naturally, so far as may be, the speakers discuss electric vehicle service.

The January meeting of the section, however, will be held at Salem Jan. 15, and to arouse the interest of the people there will be a parade of passenger cars and service wagons through the streets of Salem, Beverly and Peabody, the start to be made at 3 o'clock. At 6 o'clock the members of the section and others who may join them will have dinner at the Salem Club. Beginning at 7:30 there will be a parade of illuminated vehicles through the business district of Salem, and at 8 o'clock a public meeting will be held at Board of Trade hall, to which the public is invited. The speakers will include Harry F. Thomson of the Research Department of the Massachusetts Institute of Technology, men who are engaged in the sale of electric passenger cars and service wagons, and Frank J. Stone and George W. Holden, who represent battery manufacturers.

Manager S. Fred Smith of the Salem Electric Lighting Company has planned to entertain the central station representatives, and all out of town owners who desire to have their vehicles participate in the parades will have free current and garaging by application to the company's garage.

A department will be given over to the exhibition of automobile vehicles to be made in Pittsburg, Penn., Feb. 14-21, under the auspices of the Pittsburg Auto Show Association. Space has been assigned to exhibitors of 72 different makes of machines. The display will be made in Exposition hall, which is a permanent structure in the centre of the city, having ample space for every purpose required.

Purchasers of Stegeman trucks will from now on have option of chain cases, as the machines will be built with open and enclosed chains as may be desired.

ELECTRIC BREWERY WAGONS.

Special Body Equipment Designed by the Baker Motor Vehicle Company.

For the use of brewers who require light delivery wagons for the distribution of bottled products in small towns and the residential sections of cities a special body has been produced by the Baker Motor Vehicle Company which, while primarily intended for installation on a 3000-pound standard electric chassis, can be built for use with 2.5 or four-ton machines, the bodies differing only with reference to dimensions. The design is a full enclosed type with a roof extension even with the dash, and panels at the sides of the driver's seat, in which are large windows.

For the 3000-pound wagon the body is built with loading space 106 inches length, 46 inches width and 60 inches height, in which 54 24-bottle racks can be placed. At either side is a sliding door half the length of the body, but the rear end is closed. The doors slide on rollers on overhead tracks, which insures against obstruction of movement, and each is secured by a spring lock that requires a key to open when closed. The arrangement of the doors is such that the driver can remove any part of the load without moving the cases. As the filled cases are removed and empty crates loaded there is convenient access to the load at all times. The floor is inclined toward the centre to insure against the cases sliding against and preventing the convenient movement of the doors. Loading and unloading can be done very quickly with these bodies.

The Erie Brewing Company, Erie, Penn., was the first to use this type body and it has given much satisfaction, being extremely serviceable from every point of view. During a blizzard in Erie in November this company's machines made regular deliveries when other machines and animals were not worked. The

electric machines have not been out of service a day since use was begun nearly a year ago, and have been found to be very economical.

The body designed for the 2.5-ton chassis will carry 90 24-bottle crates, and the four-ton body will carry 145 cases. Besides this form of body the company builds the equipment that is recognized as standard for brewery service, for either keg or barrel delivery.

BOOMING THE LINCOLN HIGHWAY.

The promotion of the Lincoln national highway will be systematically done the present year by 26 different publications devoted wholly or in part to motor-ing, to the motor vehicle industry, the trade or to highway haulage. Each of these prints will publish gratuitously during the year advertising that will aggregate six full pages, making appeal for funds for general construction purposes. The advertising copy will be written by men of national reputation among advertisers, who will contribute their services to the cause.

The advertising will appear in the different issues of the magazines, according to the judgment of the men who will prepare it, and it will be especially interesting from the fact that the projectors of this concerted publicity hope to be able to secure subscriptions to a total of \$200,000 during the year. The funds will be sent to the Lincoln Highway Association. The magazines are located in all parts of the United States and Canada, and the MOTOR TRUCK, Automobile Journal and the Accessory and Garage Journal are included in the list.

"OIL TOPPINGS" WELL TESTED.

The value of "oil toppings" as a motor fuel was well demonstrated at the recent Los Angeles, Cal., motor truck exposition, when a KisselKar truck motor was run practically continuously for 128 hours, the engine being stopped twice for a few seconds. The motor was driven at what corresponded to 20 miles an hour and to a total mileage of 2560, and when the spark plugs were removed some encrusted carbon was found on them, but no soft or spongy deposit. During the test a new carburetor, made at Los Angeles, was used, and the result was official verification of the trial of the same fuel during which a KisselKar truck was driven from Los Angeles to San Francisco, a distance of 472 miles, for an expense of less than \$1.40. Oil toppings is sold at three cents a gallon.

Special Body Designed for Carrying Cases of Bottled Beer for Installation of Baker Electric Wagons and Trucks.

ONE RECEIVER FOR POPE COMPANY.

Col. George Pope is serving as the sole receiver of the Pope Manufacturing Company in Connecticut, this being the result of a decision by Judge Case of the superior court on the petition heard by him at Hartford, Conn., brought by Boston stockholders, who sought to secure the appointment of Charles A. Morse and Charles A. Persons of that city as co-receivers. Col. Pope was originally appointed and later the petition was introduced as the result of a meeting of Massachusetts interests. Immediately after this determination manufacturing was resumed and the activities of the company planned.

ANNUAL CHRISTMAS TREE.

Santa Claus made his annual visitation to the members of the Electric Motor Car Club of Boston at a meeting of that organization at the Hotel Thorndike Dec. 22, L. R. Vredenberg assuming the role of St. Nick. Each member received a filled stocking from a reindeer, and the gifts were selected especially for the recipients. The occasion was extremely pleasureable.

M. & A. M. OFFICERS RE-ELECTED.

The Motor & Accessory Manufacturers, at the 11th annual meeting at New York City, Jan. 7, re-elected J. H. Foster of the Hydraulic Pressed Steel Company, E. Raymond of the B. F. Goodrich Company, T. J. Hazel of the Spicer Manufacturing Company and C. Stiger of the Stromberg Motor Devices Company officers for three years, and received the reports of president, treasurer and the chairmen of committees. At a meeting of the directors held the following day these officers were chosen to serve for one year: president, J. H. Foster, Hydraulic Pressed Steel Co.; vice president, F. Hallett Lovell, Jr., Lovell-McNeill Manufacturing Company; second vice president, C. E. Whitney, Whitney Manufacturing Company; third vice president, F. C. Kings, Billings & Spencer Company; treasurer, L. M. Newright, Diamond Chain & Manufacturing Company; secretary and assistant treasurer, Ed P. Sloan, Jr., Hyatt Roll-bearing Company. William Sweet was continued as manager of the association and following were elected to membership: Couder, Paeschke & Company, Milwaukee; American Sheet & Tinplate Company, Pittsburgh, Pa., and Champion Machine Working Company, Cleveland, O.

TESTED IN A BLIZZARD.**Pierce-Arrow Truck Operated in Snow That Tied Up Cleveland, O., Traffic.**

A Pierce-Arrow five-ton truck was demonstrated during the blizzard that blockaded the streets of Cleveland, O., for several days, caused property damage to the amount of at least a million dollars, blockaded railroad and trolley traffic, and so greatly diminished the supply of food that only by heroic work were the people saved from actual hunger. The demonstration had been arranged by the Cleveland agent for the machine, who engaged to haul coal for the Zittlemeier Coal Company, and the Monday morning the work was to begin Old Boreas had deposited enough snow in the streets to practically cause a cessation of traffic. The storm continued for three days more and when the snow fall had ceased there was 22 inches depth, while in places drifts were five and six feet in height.

The truck was driven by a driver who was not thoroughly experienced, and it was worked continuously from Monday morning until Wednesday afternoon with a stop from 3 to 5 Tuesday morning and another from 3 to 7 Wednesday morning, carrying coal. The truck was loaded to capacity and it plowed through the streets with freights that could not have been moved with any other conveyance. The coal company tried to use four and six-horse teams on its carts and was forced to abandon the delivery, but the machine, which was fitted with a dumping body and hydraulic hoist, was required to deliver practically all the fuel that was sent out during the period it was worked. The motor was kept running continuously during the time the machine was in service.

The difficulty of securing traction may be judged from the fact that the truck used more than 60 feet of tire chains during the three days, the links breaking and necessitating renewal at frequent intervals.

Five-Ton Pierce-Arrow Truck with Hydraulic Hoist and Dumping Body That Was Demonstrated in a Blizzard at Cleveland, O.

"MOTOR TRUCKS OF AMERICA".

A wealth of up-to-the-minute and dependable information on the general subject of motor service vehicles is contained in the "Motor Trucks of America", volume two, which is now ready for distribution by the B. F. Goodrich Company, Akron, O. Those who own or use trucks, or are investigating transportation with motor vehicles, will find that this book has unusual value. The first volume was published a year ago, and so large was the demand that the company decided to issue a similar book annually.

Volume two includes illustrations and the specifications of more than 90 trucks built in the United States, the data and photographs being furnished by manufacturers who are stated to represent approximately 92 per cent. of the production of the motor truck industry. The information is accurate and complete, representing every essential detail.

The book is well designed and printed and contains 112 pages. It is cross-indexed and in addition to the data stated it contains a reprint of "Efficiency in Buying and Operating Motor Trucks", which was written for the Review of Reviews by W. J. McDermid. Incidentally it deals with Goodrich truck and wagon tires, giving facts of these that are desirable to know. The book may be obtained at request made to the B. F. Goodrich Company, truck tire department, Akron, O.

FALL RIVER ENFORCING STATUTE.

The board of police commissioners of Fall River, Mass., has been requested by the city council to take whatever action may appear expedient to prevent the use of large motor vehicles on the streets of the city in violation of the provisions of the law enacted at the last session of the Massachusetts general assembly. This law limits the weight of traction engines, trailers, motor or other vehicles to 14 tons unless a special permit is obtained, prohibits the use of clamps, cleats or flanges on rims or tires of wheels; prohibits the weight of a vehicle exceeding 800 pounds per inch of tire width; limits the speed of a vehicle weighing with load in excess of four tons to 15 miles an hour; limits the speed of a vehicle weighing with load in excess of six tons to 12 miles an hour with rubber tires, or six miles an hour with metal tires; and provides that permits may be general or for specified highways, or for a limited period.

The LaCrosse Motor Truck Company, LaCrosse, Wis., has elected the following officers: President, Frederick Noetzel; vice president, Herbert Lewis; secretary-treasurer, W. F. Ristow.

The Auto Tractor Company, Niles, Mich., is to erect a factory in that town that will be one story and 250 by 90 feet. Construction is to be begun immediately.

TRANSPORTATION EFFICIENCY.

The December meeting of the New England section, Electric Vehicle Association of America, was held at the Edison auditorium at 39 Boylston street the evening of the 18th, at which time an address was made by Charles F. Smith, superintendent of the garage of the Edison Electric Illuminating Company of Boston. This garage is used for housing both electric and gasoline machines and is one of the finest in the world. Mr. Smith described the service station of the company and its equipment and the system governing the transportation department, which has been the development of years of experience. Efficiency is the primary object, both in the garage and in the operation of the vehicles, and the explanation of the results obtained by careful organization was decidedly interesting. The address was illustrated by stereopticon views. President J. A. Hunnewell of Lowell presided at the meeting.

The H. W. Johns-Manville Company of New York City has entered into an agreement with the Carter Carburetor Company, St. Louis, Mo., maker of the Carter multiple-jet carburetor, to exclusively market the products of the Carter company through its branches and selling agents throughout the country. The Johns-Manville Company will, during the coming 60 or 90 days, establish service stations at all its branches where users of Carter carburetors can receive whatever attention is desired by them. Hugh H. C. Weed, vice president of the Carter Carburetor Company, will be associated with the Johns-Manville Company as manager of the carburetor department, and will be located at the branch of the company at Madison avenue and 41st street, New York City.

Cortland F. Ames, for a considerable length of time distributor of Sewell cushion wheels at Chicago, Ill., has associated himself with the Devine Tire Company of that city as sales manager. The Devine tire is constructed of cotton duck and large claims are made by the maker for its endurance and service in all working conditions.

The non-resident owners of service wagons that are driven into Illinois from other states, have been required to take out registration and driving licenses in that state. The laws relative to registration and operation are being rigidly enforced.

J. M. Bray has been named service engineer of the Atterbury Motor Car Company of Buffalo, N. Y. He was until recently connected with the Continental Motor Manufacturing Company, Detroit, Mich.

The articles of incorporation of the Otto Armleder Company, Cincinnati, O., have been amended so that the company can engage in the manufacture of motor wagons and trucks.

The MOTOR TRUCK

Devoted to Motor Driven Business Vehicles of All Classes.

VOL. V.

PAWTUCKET, R. I., FEBRUARY, 1914

No. 2

PRACTICAL MOTOR TRUCK ECONOMIES.

**Combination Service of Machines for Long and Heavy Haulage and Animals for Short Hauls and Route Deliveries Highly Satisfactory in Creamery Distribution--
Facilities and Methods Developed by Four Years' Experience.**

INCREASED efficiency and resultant economy will undoubtedly receive consideration from business men, and yet the experience has been that the majority of those owning or managing enterprises will continue a condition rather than make a change that cannot definitely be established so far as results are concerned. With reference to highway transportation, while most executives realize the possibilities, they are not willing to devote the time and attention necessary to development of them.

The fact that relative efficiency can be obtained with animal and motor equipment does not appear to be generally understood. By this is meant that quick loading and unloading, facilities for handling loads, and organization and system will be as productive with the one as with the other. The motor vehicle has usually greater speed and carrying capacity, and its utility is unchanging, while the service of the animal is limited in many ways. But as a rule not until the motor vehicles are used is there any disposition to develop productivity.

Many owners, considering propositions for economizing haulage expense, regard the proposal too broadly, and instead of adapting the equipment, using motors where these would be worked to greatest advantage, and continuing the service of horses in the event of doubt as to results, reject the subject without understanding possibilities. Where a service is reasonably constant the more definite information is obtainable, but even when extremely variable sufficiently accurate facts can be determined.

Motor Trucks and Horses.

The most practical method would appear to be the utilization of motor wagons or trucks wherever these could be used with reasonable assurance of profit

and the use of animals for such work as appeared questionable with reference to economy. That is, a part of a transportation equipment might be motorized, and by observation and record the possibilities with the animal vehicles determined by results in comparative operation.

Many concerns of large proportions are carefully ex-

Plant of the Maine Creamery Company, with Wide Drive to Stable and Garage and Loading Platform Serving for a Dozen Vehicles at the Side of the Building.

perimenting, using differing types of motor vehicles in comparison with horses. Others have combination equipment that has been found satisfactorily economical. Careful deduction from data covering periods of considerable length has established that where this form of service has been in use the efficiency is reasonably good. There are two conditions that may be met with—the continuance of methods adapted from custom with the horse, and a tendency to overload the motor vehicles because they can be made to carry overloads. Men who would not tolerate working a horse excessively will seldom hesitate to load whatever they believe they can carry, even with a strong probability of damage.

Important Factors.

Without considering instances that may be regarded as the exception and not the rule, the possibilities of working horse and motor wagons under the same administration have been productive of satisfactory efficiency. Where the executive that directed the animal service is continued in charge of the motors there is probability that results with this type of vehicle will increase with experience. To expect extreme economy with limited knowledge would not be reasonable.

There are objections to combining garages and stables, and separate establishments might be regarded as expensive. One stable or one garage would appear to be the ideal, but conditions are not often such that the two could be united save where special provision has been made to insure against fire, such as the division of a building by a heavy wall, or the use of two buildings a sufficient distance apart as would minimize danger.

Maine Creamery Company.

The transportation service of the Maine Creamery Company, Providence, R. I., is an instance of utilization of motor and animal vehicles in combination, the machines taking the place of horse equipment in suburban distribution, that is worthy of special inter-

est. For one class of work the animals are believed to be more economical than the motor vehicles, while in other classes the machines are productive of saving. The possibilities of business expansion are also especially attractive, and it is the purpose of the company to serve a considerable area of new territory the coming spring that would not be possible with horse service. Not only this, the company can give the customers it will develop quite as good attention as those within a very short distance of the office and plant.

The company's plant is at 69 Broadway and it is equipped with every facility for production, and the increase of production through the expansion of business means a realization of lower manufacturing cost, and consequently a greater profit than would be apparent if transportation only were considered. As a matter of fact the nearer to continuous operation during working days that is practical the larger the economy, and as the demand for products varies with the season the desirability of production efficiency and the lowest investment that is consistent with this are evident enough. The company deals extensively in sweet cream, which is supplied in bottles to retail establishments and quantity consumers, and in addition to this manufactured about 200,000 gallons of ice cream last year. This output will undoubtedly be considerably increased the present season.

Production and Distribution.

The production is lowest during the winter months and largest in the summer, gradually increasing from minimum at this season to maximum through June, July and August, then decreasing gradually. During December, January and February the demand is comparatively small, but as the temperature rises the consumption is such that the plant is operated until midnight in extremely hot weather. This statement is made to emphasize the extremes of demand, while of course the usual changes of temperature will considerably influence requirements for distribution.

The company maintains a plant in North Provi-

The Motor Equipment of the Maine Creamery Company, Providence, R. I., Manufacturer of Cream and Ice Cream, Used for Distribution. Installation Will Probably Be Increased and Business Expanded.

ence, about four miles distant, where it cuts and stores ice each winter, having a privilege at a large pond and an ice house with a stable and the usual facilities. The daily consumption ranges from five tons in winter to 10 tons in summer, with occasional demands in excess of these figures in the event of unusual conditions. The ice harvest is ordinarily considerably in excess of the requirement, when cutting is possible, and the intention is throughout the year to haul this ice. The company will install this winter an ice making apparatus with capacity of 30 tons daily, which will be available in the event of a shortage of ice, and which will be operated in connection with its cold storage installation at the creamery, but ice will be cut at the pond to the maximum storage limit, and the artificial ice will be marketed when not needed. Artificially made ice is not as satisfactory for ice cream packing as that naturally frozen, and while the freezing plant will insure against the high prices of a short harvest and protects the company, the haulage from the ice houses will be continued and the tonnage will probably be increased rather than decreased.

The business was established a number of years ago and has steadily increased, the distribution of sweet cream and ice cream being in a section about 25 miles in length, extending north from Providence about eight miles, south on the east side of Narragansett Bay for 16 miles, and southwest on the west side for about 12 miles. The population served is somewhat in excess of 400,000. North of Providence, in the cities of Pawtucket and Central Falls, and in the towns of Cumberland and Lincoln are approximately 100,000 inhabitants, and on the east side the towns of East Providence, Barrington, Warren and Bristol have about 35,000 residents. The other sections reached, the city of Cranston and the towns of Warwick and West Warwick, have perhaps 40,000. Roughly speaking 40 per cent of the population is outside of Providence.

The cream and the ice cream customers are not usually served by the same vehicles, the cream being distributed by one series of vehicles and the ice cream

by others, though perhaps two deliveries may be made to the same place. The reasons for this are that the means for cooling are entirely different, and the cream delivered to grocers, markets, etc., is required for family use.

Early Experimentation.

The company four years ago purchased two two-ton trucks, the intention being to use one of these for ice haulage and the other for the distribution of ice cream in the section north of Providence. The results were not satisfactory for several reasons. One was that the machines were more or less experimental and another that the necessity of sending to the factory in the event of a part renewal necessitated costly loss of service. That the maker did not maintain a service station was no doubt justified by the conditions, but unless spare parts were stocked special work at considerable expense was entailed. The trucks were utilized so far as was possible, but the expense of operating was found to be considerably in excess of what had been estimated. Despite the failure and expense they were found to have utility that prompted careful inquiry, and after two years' service a definite plan was decided on.

In this two years a system of distribution was planned that has since been developed, an organization of operation and maintenance decided on, and provision made for facilities for the housing of the equipment that was contemplated. This all entered into the general project for business expansion.

The expectation was when the original trucks were purchased that these would afford service for several years, but with the intention of reducing the horse equipment the sale of these machines was decided on. In January, 1912, the first three-ton Packard truck was ordered, the chassis only being purchased, and within a period of two months two others were bought. The intention then was to utilize one of these for ice haulage and general work that might be practical aside from this, the second to give a daily service to the section north of Providence, and the third to be operated on either side of Narragansett Bay, south of

Using Its Products Within a Radius of 16 Miles Outside of the City and for Haulage of Ice from a Suburban Storage—This Plan Developed in a New Section the Coming Spring.

Providence, motorizing the long hauls.

The requirements of the business were very well understood, and the selection of units of this size was made after careful consideration. The chassis were fitted with platform bodies with sideboards and stakes so that in the event of need the sides could be removed. The sides were fitted with removable panels that could be lifted out when desired, so that side or rear end loading was equally practicable. The decks of the bodies are of two-inch oak plank, with the seams filled with white lead, with copper gutters fitted at either side and drains that carry the water from the ice meltage clear of the chassis at the forward and rear ends of the platforms.

The Body Equipment.

The fittings of each machine, so far as the bodies were concerned, were identical, so that any one could be used for any work in distributing and ice haulage, so that should one be out of service another could be utilized. This provided for any exigency that might

was delivered early in February of last year. The body on this chassis is an express type with a standing top with grating sides and rear doors, so that it may be loaded with the greatest convenience, and this body has a floor in which the drainage is at the rear. Either box is utilized as in larger machines or the ice cream is carried in cans in large tubs packed in salt and ice, so that provision must be made for carrying off the meltage.

How They Are Operated.

In the operation of these machines, assuming a period when maximum requirements exist, one truck is loaded at the plant and driven to Pawtucket, where distribution is begun. Under such circumstances the truck will put out 250 gallons of ice cream daily. At the same time two single-horse wagons are also loaded with ice cream and driven to Pawtucket, these having similar equipment, but smaller, than the truck. They are accompanied by a single-horse wagon with a load of sweet cream. From the truck the large deliveries are made and the principal customers are supplied direct, but the wagons make deliveries of the smaller orders. Should the wagon need additional stock they are replenished from the truck, which is known to be at definite locations at stated times, and should there by any reason for delivering in excess of what is carried by the three the truck is driven back to the plant and a sufficient quantity obtained. While the truck is obtaining fresh stock the wagons continue to deliver. Normally the truck is expected to have a sufficient supply. Manager Harry F. Hardy says that as the distribution is planned for this section the

Two-Ton Packard Machine with Special Body Adapted for Side and Rear Loading, Used for Longest Hauls, Where Quick Work Is Essential.

be anticipated. Two of these trucks were fitted with boxes, the one carried forward in the body and the other carried at the rear, these being separated by a space about two feet width. In regular service the forward box is filled with heavy round cans in which the ice cream in brick form in paper boxes is packed, and the spaces between the cans packed with ice and salt. In the space between the two boxes is carried two barrels containing salt, and the rear box is filled with crushed ice, the ice and salt packing of the ice cream box being replenished as occasion requires. The meltage from the forward box contains a considerable quantity of salt, and this is drained into the gutters of the decks of the bodies and carried off into the highway. This salt would naturally cause erosion of the metal in the event it was not protected. For this reason the gutters are constructed in the bodies.

The fourth machine ordered was a two-ton Packard, this being fitted with a different type body. This

truck is as good as a branch, while customers can be given attention equal to those served direct from the plant. The truck is worked in this manner for about nine months of the year, and during the remaining three months it is overhauled and then used in the stead of the other machines during overhauling.

The second truck is used in delivery Monday, Wednesday and Friday of each week in East Providence, Barrington, Warren and Bristol, and Tuesday, Thursday and Saturday in the city of Cranston and the Pawtucket valley sections of Warwick and West Warwick, and because of the intervals between the trips the deliveries are generally larger than they are at Pawtucket. This machine carries heavy loads and it is not accompanied by horse wagons.

The third truck is used in haulage from the ice house at North Providence, making an average of eight trips daily and often nine during the hot weather, and if necessary some overtime may be necessary to

keep the supply up to the needs of the distribution.

The two-ton machine is used for all manner of work, being sent out on the Bristol and the Pawtuxet routes in the event of shortages and when the weather is extremely warm, and it is sent with all large special orders. The body equipment does not permit the use of the boxes, but the load is usually packed in tubs and a considerable stock can be handled with it. In addition to this the company makes use of a Cadillac pleasure car chassis fitted with an express body. The machine was used in 1910 as a passenger car, and the following year was converted and since that time has been used for making special trips and the delivery of orders up to its capacity. Besides this it serves to carry men about when necessary and is utilized as an emergency wagon by the mechanic in charge of the garage. The Cadillac has been driven upwards of 40,000 miles and is apparently enduring well. It will do the work of half a dozen horses because of its speed and utility.

The Horse Equipment.

Besides the machines the company uses about 20 horses, these being used practically on all of the regular routes in Providence, but they are seldom worked in teams, because of the trucks. But one horse has been bought in two years, and the number has been somewhat reduced in that time, for the business has increased and the machines have taken care of this.

Before the trucks were bought horse teams were used and of course the number necessary for the routes varied with the work, but usually the animals were kept the year round. If horses were purchased in the spring they would show the effect of the hard work during the season and would shrink badly in price if offered for sale, and they could be brought back by easy work into condition for the following year. In some instances horses were turned over to concerns that kept and worked them during the winter, but this was not satisfactory, for those using them generally failed to give them the care they ought to have to preserve their usefulness. The cost of keeping the horses during the winter was considerable and they were practically worked only sufficiently to exercise them.

The out-of-town routes were all hard on horses during the busy season, for it was necessary to use those making Bristol and the Pawtuxet Valley routes alternate days, the trips being from 35 to 40 miles, and rest every other day was imperative. In the ice haulage a four-horse team hauled six tons, making two round trips of eight miles daily, and in addition horses were hired for this work each summer, for the consumption of ice was largely in excess of the 12 tons hauled by the team. At that time the driver started from the ice house at 4, having to rise at 3 to feed his team, and he had a long day when he put up at the ice house stable for the night. During the summer one truck is kept at the ice house and the driver, starting at 5:30, can make eight or nine trips, the mileage being from 64 to 72 miles, and the average time for the run between the ice house and the plant is 20 minutes,

as against the hour and a half for the team with a load and an hour and a quarter light. With horses the two-horse teams made two trips with three-ton loads. Figuring capacity loads the truck is equal to two four-horse teams and two drivers, or four two-horse teams, to say nothing of the reserve capacity in the event of need.

Comparative Results Obtained.

The trucks have been used longer in Pawtucket and the Blackstone Valley than any other section, the first one being placed in service there, and the regular mileage will approximate 40. Previously, horses were used, but the business has so much increased that comparison cannot be made on the basis of work done with them. The truck covering the Bristol route makes 45 miles or more three days in the week, and about 40 miles the other three days on the Pawtuxet Valley route. The two-ton truck will vary considerably in its work, but it is driven an average of 50 miles daily during the busy season. Considering the numerous stops made the machines are driven very consistently and there is little idle time for them.

The loading and unloading of the ice truck is not as rapid as might be possible with other work, for the force of men at the ice house is necessarily limited, and the load is handled with reasonable care. Unloading, the ice is pushed from the truck platform into a chute and is carried by gravity to the basement of the plant for storage. The loading facilities for the trucks and wagons are well arranged. A long platform extends the length of the building and a dozen vehicles can be backed to this, with room for others to pass in front of them.

The ice boxes on the trucks are filled by gravity with crushed ice, that is, carried from a crusher in the basement by buckets to a chute that can be swung over the vehicles, and the salt barrels are also filled by gravity from a large bin on the second floor. The loading platform is level with the truck and wagon floors and but little time is required, for the filled cans and the packed tubs are ready for the crews to handle. A line of vehicles can be placed along the platform and side loaded with but little waiting. The loading as a rule is done in relays in the morning, and after the starting is made in the morning there is no reason for delays.

Stable and Garage.

The stable and the garage are in the rear of the plant, the property extending back to Atwell's avenue, and the garage is in the basement of a large building that has been specially fitted for this purpose. It will store 10 machines and there is abundant room for expansion. Part of this is to be fitted as a repair shop. The garage is in charge of a mechanic whose work is to keep the machines in operation. This may mean day or night labor and he is expected to do whatever is necessary, assistance being given him when occasion demands. The garage has an equipment of hand tools and facilities for doing practically whatever may be needed. Once each year the trucks

are given overhauls and placed in the best of condition and this work is done when the conditions for work will permit. In the event of road trouble the driver notifies the mechanic and the Cadillac is sent out with whatever may be needed to make a temporary or even permanent repair, and usually there is no need for transferring a load.

As a safeguard against accident a spare front and a spare rear wheel for the three-ton machines, and a spare radiator are kept in the garage, and these have been found exceedingly useful, the wheels in the event of tire damage, and the radiator should a leak develop. With these replacement can be made in comparatively short time and the machines started, while without them the service of a truck might be lost for a period that would mean considerable loss.

As to Outside Work.

Manager Hardy says that he has done enough outside work each winter to pay for the repairs of the trucks, this varying from the haulage of several thousand barrels of apples to carting gravel, while one truck makes one or more trips a week from the Builders' Iron Foundry to the United States arsenal at Wattertown, Mass., carrying castings that are used in the construction of government military equipment. The machines have earned from \$1200 to \$1500 each winter, which has been a very convenient fund when maintenance is considered.

The advantage of the machines as compared with animals in the service of the company is that when they are not operated the expense is small and they are not deteriorating in value. Animals cost practically the same whether they are worked or not. If the work is light the operating cost and the maintenance expense is correspondingly small. This is a factor of material importance. The fixed charges go on, but the labor cost ceases.

Mr. Hardy says that the cost of operating the trucks, three-ton size, will closely approximate \$10.50 a day when new, and that as the service is continued this will increase to about \$12 a day. There is but little variance from these figures in normal service, although if the mileage is increased there will be proportionate fuel and tire expense, and this will be reflected in the maintenance cost as well. His experience, however, has shown that the cost stated is very close to what may be expected under similar conditions. While his mileage is probably large, yet his maintenance and overhauling expense are relatively low because the attention is constant instead of casual. He believes that he will be able to realize seven years' life for a truck because of the care given, and that they are driven by careful men. He educates his own drivers and he has found that men who have driven horses are reliable and responsible. Practically every driver in his employ, including those driving horses, have licenses to drive machines, and he does not have occasion to use untried men. This has been found to be a very good safeguard and protects him in the event of sickness or accident. And each horse driver is

anxiously awaiting promotion to driving a truck. This has placed a premium on the truck driving, and each man regularly working a truck is as anxious to keep his employment as the others are for opportunity to do such work.

Manager Hardy says that he would have to use a very much larger number of horses than he now uses were he to operate with the former conditions, he would not be able to do the work as economically and he would not satisfy his customers, this applying, of course, to work outside of the city. Within the city, with the short routes and the numerous stops, he does not believe that he will come to machines for a long time, because of the need of a decidedly cheaper method of haulage than he has realized with the trucks he now has in use. The Cadillac machine is not operated with a view of economy, but for the purpose of conveniencing patrons and serving customers whose business is valuable. In some instances the cost of delivery is much more than the profit, but this work is credited to promotion and the cost is so regarded.

ASSETS EXCEED LIABILITIES.

The assets of the Brown Commercial Car Company, Peru, Ind., which is now in the hands of a receiver, eliminating every item not having a tangible value, such as good will, etc., show a total of approximately \$126,000, while the liabilities, which amount to about \$100,000, are in part secured by notes pledged on unfinished machines, and which must be completed to have a substantial value. Included in the liabilities is a mortgage for \$47,000 on the real estate. The company has never recovered from the effects of the flood in that section of the state last spring, which did a great deal of damage to the factory and materially delayed the production of machines that had been ordered.

LISTENED TO GYROSCOPICS.

"Gyroscopics" was the subject of the meeting of the Metropolitan section of the Society of Automobile Engineers which was held the evening of Jan. 29 at the house of the Automobile Club of America in New York City. A paper was read by E. P. Hopkins that was descriptive of the use of the gyroscope in the operation of the Hopkins monorail railroad system, that was of material interest from an engineering viewpoint, and a discussion was opened by Edward Durant which considered the scientific value of the gyroscope.

A two-story building, covering an area about 200 feet square, of mill construction, is to be built at Winton Place, O., by the Victor Auto Parts Company. The addition will practically double the production of the concern.

TRUCK MAKERS FIX USERS STANDARD.

Specify Body Dimensions and Weights, Load Capacities, Rates of Speed and Charges for Demonstration, with Recommendation of Adoption---Will Improve Sales Methods.

THE manufacturers of motor wagons and trucks have principally directed their endeavors to the production of vehicles that from the viewpoint of the engineer are well designed. The concerns that are well established build machines generally developed from a standard. Scientific methods are employed in manufacturing, and extreme care has been taken to insure the quality of the vehicles produced. Theory has been supplemented by experience, and wherever necessity has justified improvement has been made, although most engineers believe that standards are desirable, both from the standpoint of manufacturing economically and the uncertainty of experimental productions.

The attitude of the manufacturer with reference to distribution and the attitude of the buyer as regards the maker are not antagonistic, but the builder makes machines that are intended to meet certain requirements and the purchaser believes that he can do work often largely in excess of the capacities provided for by the engineers, the result being that, with a guarantee of factory perfection, the owner demands that the vehicles be kept in repair and in condition for service, no matter what the conditions for use.

The manufacturers of service vehicles, in many instances builders, or former builders, of pleasure cars, have assumed that owners of wagons and trucks will use their property with the same care and discretion that would be exercised with any other property. In this they have applied the usual measure of common sense and assumed ordinary prudence, but the owners, often believing that they were getting something for nothing because of overloading or fast driving, have countenanced what is destructive. Were the o-

ners the only ones to suffer the consequences of their negligence or poor judgment one might not reasonably make protest against their acts, but every interest is affected, and to a degree that is serious.

Standardization Policy.

The condition stated is by no means new, but the results have been so pronounced that the industry, as represented by the National Automobile Chamber of Commerce, Inc., has undertaken to define a policy in dealing with buyers of motor vehicles that will be equitable for manufacturer, selling representative and owner, and when uniformly maintained will be materially beneficial. This does not mean that the manufacturers desire to deprive the owners of what any business man would consider himself morally obligated to supply, but it does mean that the industry has realized the necessity of defining to what extent it is responsible to the business men who use machines.

In determining this policy a series of standards was arrived at by the commercial vehicle committee of the chamber, and this has been prepared in form for transmission to each active manufacturer with the suggestion that the standards be approved and incorporated in the records of each sale consummated in future. The committee has authorized the distribution of sets

of seven cards which show the different standards recommended in 1912 by the National Association of Automobile Manufacturers, the cards being eight by 10 inches in size, printed on one side, and centre-scored so that they may be filed flat in a letter file, or folded once and placed in a five by eight-inch card index file. Each card relates to a single subject, so

Standard Form of Warranty for Commercial and Passenger Vehicles, Approved as to Form Dec. 3, 1913, by the National Automobile Chamber of Commerce.

Resolved, That in the opinion of this meeting it is inadvisable to encourage the belief that a truck is designed to carry any weight in excess of its rated capacity, or to permit a warranty to apply on any truck which is overloaded, and this meeting recommends that a standard plate be prepared for the chassis to indicate the load capacity.

No Overload Allowance Resolutions, Approved by the National Automobile Chamber of Commerce.

that the series can be separated and cards distributed to the different departments of a factory to which they relate.

Subjects Dealt With.

The subjects dealt with by the cards are: Standard warranty, standard speed rating, body weight allowance, standard overload allowance resolution, standard caution plate, standard frame widths and length and standard demonstration charges. The warranty is a new form, adopted Dec. 3, 1913, and supersedes the motor truck warranty by the National Association of Automobile Manufacturers in 1912. It is a combination of this warranty and the standard for passenger cars adopted in 1910, and it applies to both passenger and freight vehicles.

The tables of speeds, body weights, frame dimensions and demonstration charges are accompanied by charts or curves corresponding with the figures. The caution plate against overloading and fast driving and the standard warranty are illustrated by half-tone engravings. Prices for the plates and warranties are stated. These cards have been sent out to each firm of record as a manufacturer of motor wagons or trucks with the suggestion that the prompt and general adoption of these standards will promote the best interests of the industry. At request it will supply cards to any who fail to receive them, or to organizers of companies that are about to begin production.

Considering these recommendations in sequence it may be said that the standard warranty is intended for use in connection with the standard caution plate to be placed on all machines, but for the proper legal protection to the manufacturer, the warranty should be made a part of the contract of sale by printing the form on all order blanks, preferably on the face, and referring to it in the order by some phrase as the following:

"It is understood that no warranty, either express or im-

plied, attaches to this sale other than that expressed in the standard warranty, approved by the National Automobile Chamber of Commerce, Inc., which is printed above (on the back hereof) and that there are no understandings, agreements or representations not specified herein or in the said warranty respecting the subject matter of this sale."

With relation to the standard speed rating, it is recommended that this be adopted

by the manufacturer, together with the standard warranty and standard caution plate; that the machines be designed to be driven at these speeds as maximum and that the warranty be withdrawn in the event of flagrant violation by the user; that the weight of bodies, whether built by the vehicle manufacturer or by a body builder to the order of the purchaser, should be kept within these allowances, and that any excess of weight above the allowance should be deducted from the rated load capacity of the chassis as indicated on the caution plate.

With reference to the resolution relative to no overload allowance it is stated that in passing this resolution, and adopting standard speed ratings, standard body weight allowances, standard warranty, standard caution plate warning against overloading and fast driving, and standard demonstration charges, the manufacturers hoped by concerted action to reduce, if they could not eliminate, the more common abuses from which the motor truck industry has suffered.

The Standard Caution Plate.

The standard caution plate is to be nine inches width and three inches length, etched on 16 B. & S. gauge rolled brass, with letters recessed and filled with red and black enamel. The accompanying example shows how the figures should be filled. Those that are constant for a given number of machines can be

dered put on by the plate maker, but the variable figures must be stamped in by hand with steel dies. These variants are the truck number, the actual capacity and the actual body weight. The total weights in both columns should be the same. The adoption of the speed rating is urged, but if not adopted the rated maximum can be used. The figures referring to body weight in the standard column should agree with the recommendation, but those in the actual column should give the real weight of the body, and the difference between the two should be added to or deducted from the rated load capacity and the resultant figures stamped in to show the actual load capacity. The catalogue rating of maximum load should appear in pounds in the first column and the figures in the second column should be the sum or difference of this plus or minus the difference between the actual body weight and the standard body weight allowance. No provision is made for overload capacity. The chassis weight is the weight as built by each manufacturer and may vary with wheelbase, frame length, equipment, etc. The total weight is the sum of the three

Load capacity		Body weight allowance
Tons	Pounds	Pounds
$\frac{1}{2}$	1,000	600
$\frac{3}{4}$	1,500	750

9	18,000	2,200
10	20,000	2,300

sets of figures above it and should be the same in both the standard and actual columns. This is intended to inform the representative of the manufacturer or the tire maker at a glance, after driving the loaded machine on a scale, whether or not it is overloaded and the warranty invalidated. The standard frame lengths as adopted are independent of chassis load capacity, and the chart merely shows the relation of the average frame lengths back of the seat to rated capacities as found in prevailing practise. The manufacturers are urged to instruct their sales departments, branches, dealers and agents not to give or offer any free demonstrations.

Matter of Salesmanship.

As understood the action of the National Automobile Chamber of Commerce practically means that the firms included in it will adopt the standards. That other concerns will accept them there is little doubt. While a number may not do so, there is reason to believe that within a comparatively short time the policies as to conditions of sale and guarantee will be practically uniform. This being so, the sales organization will be placed on a more nearly equal basis. And naturally the matter of salesmanship, how the salesman shall represent the manufacturers, his repre-

sentations to the purchaser, and the conditions that he shall meet with are of unusual importance.

How sales propositions shall be made to business men is a subject of vital importance to the motor vehicle industry. That the real problem of the day is not so much manufacturing as it is selling is a statement not too broad. Engineering knowledge and experience have produced substantial and enduring machines, although there are undoubted possibilities for development, and design and construction are largely based on well established fact. But the selling department of each unit of the industry must deal with new propositions successively, never with two alike, and applying the same principles differently, in every instance with the one purpose of economizing.

There are those who will maintain that this is idealism, and that a practical salesman will dispose of machines as any other product is sold, the utility of the vehicles being whatever can be realized by the owners. That is, a man who is experienced will sell motor vehicles upon their face or known value to the public, and the purchasers must develop uses that

Chart Showing Standard Body Weight Allowances for Commercial Vehicles, Adopted by the National Automobile Chamber of Commerce.

will result in profit. But the purpose of this article is to demonstrate that sales campaigns have had destructive and not constructive results in frequent instances, and that instead of developing business of large volume and substantial character dissatisfaction and distrust followed the enthusiastic but poorly directed endeavors of salesmen.

Early Sales Methods.

The reason for this is not difficult to determine. Considering for a moment the progress of the pleasure car industry one may recall when it was necessary to convince a purchaser that a machine could be operated, that it was practical, that it could be driven a reasonable distance without failure, that it had speed, that it had climbing power, and that it was comfortable for the passengers. One may be inclined to smile at the assumption of mechanical knowledge by the buyers, the estimate of value of differing constructions, the hair-splitting relative to the merit of inconsequential detail of design, and the large claims often made for innovations, but one cannot deny that all of these factors were soberly regarded and assumedly appraised with care by the people who consid-

ered them as real factors when purchasing.

In the first instance the people demanded demonstration of practicality, and followed this by requiring observation and information, usually listening to the arguments of the salesmen and consulting friends with experience before deciding to purchase. With many salesmen the principal object was to create interest by extravagant claims for excellence of design, construction, power, endurance, economy, comfort, and by discounting the quality of every other machine that might be regarded as a close competitor. In brief, they sought to sell by methods that created distrust in every other machine that might be regarded as a possible subject of inquiry by the prospect. As might be assumed, experience with a few salesmen resorting to these methods frequently discouraged those desirous of purchasing, and sales that could have been made were deferred. With pleasure cars, however, amusement and recreation were the principal purposes to be served, expense of operation was secondary, and

Chart of Standard Frame Widths and Lengths for Commercial Vehicles, Adopted by the National Automobile Chamber of Commerce.

length of service depended upon fancy rather than upon period of utility.

The First Power Wagons.

The first power wagons were pleasure car chassis equipped with service bodies. In some instances trucks were constructed, but these were the exception rather than the rule. They were sold incidental to passenger vehicles and so far as the builders were concerned were not considered after the delivery to the purchasers, who were expected to utilize them as judgment dictated. Later came the specially built wagons and trucks, and the general argument that they could be used in the place of so many horses, wagons or carts and men. Greater speed and larger capacity were claimed to be the qualities in which motor vehicles were superior to horse drawn, and the general application was that in a given time a stated freight could be carried further, or increased tonnage hauled the same distance. But the salesmen soon learned that the expense of operating horses varied materially, and when endeavor was made to ascertain the cost of operation of animals definite data were almost impossible

to obtain, for very few of the many thousands of owners kept accurate record.

In fact, the condition has not materially improved today, even with the careful and consistent endeavor of the most progressive interests of the industry to ascertain precise information, and a very large part of the statements prepared have been based on estimate rather than on actual figures.

Training in Other Lines.

Salesmanship as applied to the motor vehicle industry has been different than that of any other that might be mentioned. The average commercial salesman is first carefully trained with relation to qualities and merits of what he has to sell, perhaps beginning with the purchase of the raw material and continuing through the different processes of production, and the policies of the firm, as well as accurate data as to its relative market value compared with other products. He is expected to have a knowledge of his competitors and their products and methods, and can make accurate estimate of the values of whatever he may be brought into competition with on the basis of the public demand and consumption or use.

Frame width, either 36 or 42 inches, for all sizes of commercial vehicles, measured back of seat.

Frame length, back of seat, to be in full multiples of feet and half feet from 4 to 8 feet, thus:

Feet	(equivalent to)	In.	Feet	(equivalent to)	In.
4	(equivalent to)	48	11½	(equivalent to)	138
5	(equivalent to)	60	12	(equivalent to)	144
6	(equivalent to)	72	12½	(equivalent to)	150
7	(equivalent to)	84	13	(equivalent to)	156
8	(equivalent to)	96	13½	(equivalent to)	162
8½	(equivalent to)	102	14	(equivalent to)	168
9	(equivalent to)	108	15	(equivalent to)	180
9½	(equivalent to)	114	16	(equivalent to)	192
10	(equivalent to)	120	17	(equivalent to)	204
10½	(equivalent to)	126	18	(equivalent to)	216
11	(equivalent to)	132			

No matter what the article, object or service sold, the salesman is expected to be so well informed that he can meet all on equal footing through his ability to convince the buyer of the worth of what he has to sell. In many instances personality or intimate knowledge of the man approached may be material factors in selling, and there is a human element to be considered that it is impossible to estimate. The point made is that the salesman for practically any business of consequence has been educated in what experience has taught is well for him to know, and he is not entrusted with selling until his ability and resourcefulness have been reasonably well established.

Knowledge of Design and Construction.

But the motor vehicle salesman ought to have the same sort of a training as the man who is selling any commercial proposition. He ought to know power wagons and trucks from every angle. He should have a good knowledge of the design and construction of every machine in the market of the type or types he sells. This information will be exceedingly valuable if rightly used, for he can fortify his own selling talk by statements that are well founded. Mechanical principles are clearly established and sound engineering does not require more than the application of them, but to be able to demonstrate the value of a construction

is a decided asset. An engineering education would be extremely useful for every motor vehicle salesman, although not a necessity.

The man who can discuss the machine he is selling with the satisfaction of the man who may have expert mechanical knowledge, or who can correctly inform the man who is not versed in mechanics, may be said to be reasonably well prepared to meet all inquirers between the two extremes, and insight into manufacturing processes, with understanding of the relative values of design with reference to construction, accessibility, convenience of examination or work, and economy of operation, adds to ability to meet situations that may be developed.

Market Is Limited.

Considering the salesman for motor wagons and trucks, he has first of all a limited market. All who are engaged in business, all who maintain delivery equipment, have not the resources to purchase and maintain motor vehicles, even if they have work in which these would serve a useful purpose. Apparently prosperous, a man doing business may be weighted down with indebtedness, and struggling to keep from

bankruptcy, while the concern that is seemingly lacking many characteristics attached to prosperity may have business sufficient to justify large investment and ready cash to pay its obligations. The salesman must select those who are the probable prospects if he would concentrate his endeavors. This means he ought to have some knowledge of the different firms, the extent of their patronage, the needs so far as transportation is concerned, and the service that is utilized. This should be acquired preliminary to an approach, for it is evident that if the concern is worthy of attention the salesman ought to be prepared to go to the executive with something more than the proposition that a wagon or truck be bought because the salesman has them to sell and really needs the money he would obtain if the business man would make investment.

The majority of the power wagons and trucks in service today has been sold by men who convinced their customers that theoretically motor vehicles were practical or economical, but the consummation of the sales ended, for the time being, their concern in the machines and their owners. Such salesmen sold as did the pleasure car agents of a few years ago. With them it was a matter of earning a salary or commis-

sion, and so far as they were concerned all interest ceased immediately upon payment of the price.

The Making of Promises.

From the viewpoint of these salesmen the main object was to sell a vehicle, and with the assumption that purchasing was intended and that should the inquirer leave, the opportunity was lost, every legitimate, and sometimes questionable, means was resorted to to conclude a transaction. By this is meant that salesmen, often desperate to make sales, did not hesitate to make promises or assurances, obligating themselves or their employers to whatever they believed was necessary to convince the customers. The sale meant that the salesman had assured himself of the temporary continuance of his salary, or had secured a commission, and the agent had disposed of a vehicle, this justifying the assumption that another order would be placed with the manufacturer.

Motor wagons and trucks could not be sold like pleasure cars. In rare instances a man might be willing to pay a deposit and sign an order without the preliminaries usually regarded as necessary. The

Chart Showing Standard Speed Rating for Commercial Vehicles Adopted by National Automobile Chamber of Commerce.

agent who invested his money in a demonstrating machine usually found that educating people to possibilities of power equipment cost money, and unless vehicles could be sold the outlook was not encouraging. There is no doubt that sales came much too slow for the general satisfaction of those engaged in selling, and without doubt business desperation forced many into making concessions and obligating themselves beyond what had been anticipated or expected by the manufacturers.

So far as the salesmen were concerned, promises might be made from the belief that the agents would not be required to fulfill them, and often when demands were made by the owner the agent made such adjustment as he could and in turn looked to the manufacturer for compensation under a guarantee. Sometimes the assurances were given without the knowledge or even against the orders of the salesmen's employers. The wrath of a disgruntled customer was even more feared than now, and adjustment of the difference could only be reached by compromise. The writer has known of instances where a man holding an

agency has offered a demonstrating truck at a substantial reduction in price with the purpose of selling and discontinuing the business, although he was aware that his offers would probably materially affect the business of the man who might succeed him.

Logically, at least, the acts of the salesmen are reflected upon the employer and eventually upon the manufacturer, and without doubt many a machine has been condemned simply because the owner believed that he was entitled to receive practically free maintenance.

Knowledge of Highway Transportation.

The motor truck salesman should have as comprehensive knowledge as he can acquire with reference to highway transportation, for this will qualify him to deal with the primary conditions that must be considered when a proposal is to be submitted. The man who bought a machine because it would in theory do more haulage in a given time than horse equipment might have found from experience that it would be equal to expectations if it could be worked to capacity, but the one essential was the necessary work. That

Chart of Standard Demonstration Charges for Commercial Vehicles, Adopted by the National Automobile Chamber of Commerce.

is, salesmen have sold and business men have bought wagons and trucks without accurate knowledge of what capacity was required.

The salesman was willing to sell whatever was wanted and left this to the judgment of the purchaser. The larger the price the more his credit for the sale. The buyer, however, found that he had a vehicle so inadequate that it was constantly overloaded and abused, or so large that his cost of haulage was increased beyond what he had reason to expect. The question might be asked: Why should a business man be so misled? And reply can be made that it was entirely reasonable for him to assume that the salesman had the same knowledge of the subject of transportation that any other man might have of a business he represented as a selling agent.

Following this line of reasoning one might maintain that a business man ought to be equally well informed of every detail of his business, but when one understands that the acceptance of a condition largely from custom was not real indifference, but an assumption that further economy was not practicable, this condition is not strange.

The representative of a manufacturer of a machine

that will cost from \$1000 to \$5000 cannot be compared to the salesman who is selling trucks. The former is well trained and he visits men who at least might use what he is selling. He interests the principals whom he meets because he is dealing with what can be profitably utilized. His market may not be large, but it can be developed. The competition is not general. He may have to do missionary work, but there is the prospect of material benefit later on. The latter, however, must necessarily educate his prospective customers to the necessity of economy. Generally they have capital invested in equipment and facilities, and in many instances they believe that they must sacrifice this if they are disposed to make a change.

There are those who have large haulage requirements who believe that the only practical determination is to work animal and motor vehicles in the same service for a considerable period of time. Some of the largest users of machines are men who worked those first purchased from three to eight years before they were fully convinced that the change would be economical. The salesmen who sold the initial motor ve-

Load capacity		Demonstration charges per day of 10 hours
Tons	Pounds	
1/2	1,000	\$10.00
1	2,000	10.00

8	16,000	23.00
9	18,000	24.00
10	20,000	25.00

hicles were delighted to even secure an order, but those who took the later orders had a comparatively easy task and with relatively brief intervals between sales.

Need of Efficiency Experts.

But the industry is facing a problem that has been developed by the education of salesmen, and that is the necessity of securing the services of those who are sufficiently well informed to analyze a transportation service and determine what types of vehicles, what number and what capacities are necessary to do its work; what facilities are necessary or desirable, the arrangement of these, and to organize the workers and create a system by which the department shall be administered. The suggestion has been made that some companies can profitably enlist such men and have them plan and create on what has been developed by the selling force. These men might be rated as transportation efficiency experts and as such they would command adequate salaries, but such services could not be expected from men who do the preliminary work.

By this is meant that there is a vast difference between the salesman and the man who develops efficiency and economy. The salesman, however, must

ecessarily be the man who has the qualifications to get men of affairs, who has the knowledge that will make possible the presentation of practical uses of motor equipment, and who can stimulate interest. There are those who have realized the value of expert transportation men and are willing to pay well for the oversight of departments.

But where there is one comparatively large installation there are hundreds where one or several vehicles would meet all requirements, and these are the prospects that must be dealt with by the salesman. Naturally this means that they must have ability to judge conditions of use, suggest methods of operating, and if desired exercise supervision to whatever degree will satisfy. The motor truck salesman who in seeking business intimates that the owner does not economically direct his own business may learn to his sorrow that the intimation has provoked resentment, and yet to prove his own case he must establish that economy is not only possible but practical.

The motor truck salesman must be able to establish confidence in what he is selling, and he is often confided business methods and facts that cannot be used by him indiscriminately. Frequently men will say that any publicity relative to their haulage services will be used advantageously by competitors, and they will not consent to its free distribution. Nor is it probable they will give to those engaged in similar businesses facts that they believe will be profitably used by their business rivals. For these reasons the salesman is often compelled to observe confidences that preclude the utilization of information that would be extremely valuable.

Operating records of concerns undoubtedly convey to those who might desire to know very accurate knowledge, and while in some instances these cover periods of several years, as a rule the facts obtainable are for such brief intervals that these may not be convincing to those who may depend upon them to justify investment of considerable sums of money.

The problem of the salesman, who must create business, is vital to the industry, and to meet with a reasonable measure of success these agents must have special training and capacity. The more knowledge they possess of a large number of businesses the better they are fitted for the work. The salesman meets with new conditions with each prospect, and he must be capable of convincing those whom he approaches that his propositions are practical. He must be able to satisfy his customers and continue his relations with them, and this means that he must have the support of his firm. The motor truck must be sold as an object of standard value and utility, with such guarantee as the maker shall give, and beyond that, so far as its operation is concerned, it must be maintained at the expense of the owner. In all phases of utilization, to secure economy and efficiency, the salesman can be a potent factor, and he can exercise an oversight for his customers that will be of substantial advantage to his firm and to the owner of the machines.

MARSHALL EXECUTIVE SECRETARY

New Official Named by Electric Vehicle Association Assumes His Duties.

The promotive work of the Electric Vehicle Association of America has become so diversified and of such volume that the officials have created the office of executive secretary and named A. Jackson Marshall to direct the normal activities of the organization. Since the formation of the association the work has been conducted by the officers, who have accomplished much considering the limited time they could devote to the work, but the demands became such that they could no longer continue this policy save at sacrifice of their own business interests.

The creation of a permanent secretary was recommended at the Boston convention in 1912, but in the interests of economy the officers deferred action until the time came they could no longer continue. With the appointment of Mr. Marshall a system has been devised that will insure the concentration and expedition of the work. Mr. Marshall was until recently identified with lighting companies and has a broad and comprehensive knowledge of central stations. For several months previous to his appointment he had been associated with the General Motors Truck Company, being in charge of the business interests of this company in northern New Jersey, with offices with the Electric Garage Company at 123 Washington street, Newark, N. J. The headquarters of the Electric Vehicle Association have been established in the United Engineering Societies' building, 29 West 39th street, New York City, and Mr. Marshall is in charge.

It is the purpose of the officers to undertake plans that had previously been impossible because of the limited time that could be given them, but now Mr. Marshall will devote his energies to these and to the demands that have multiplied with the increase in membership and scope of the organization.

BUYS 24 PACKARD TRUCKS.

The Loose-Wiles Biscuit Company, a concern operating bakeries in a number of cities, has bought 24 Packard machines, 13 of the three-ton type and 11 two-ton, which will be utilized in connection with the mammoth new plant the company is constructing in Brooklyn, N. Y., and which will probably be ready for operation about June 1. The company is using Packard machines in Boston, Chicago and Kansas City.

With a force of about 125 men the factory of the Milwaukee, Wis., Motor Company, now the property of Harris Bros., of Chicago, is now in operation, after cessation of production last June because of bankruptcy. The intention of the new owner is to make the property profitable and dispose of it.

FEDERAL SALES CONVENTION.

Distributing Force Forms Organization to Promote Selling and Service.

A convention of the sales organization of the Federal Motor Truck Company, Detroit, Mich., was held at the factory in that city, Jan. 19-21, and aside from the systematization and harmonizing of methods and policies with a view to better directing the endeavors of the agents and representatives, a result was the formation of an association of distributors that is expected to be productive of decidedly practical and beneficial results.

The convention was attended by upwards of 50 dealers, who came from all sections of the country, from the Atlantic to the Pacific Coasts, and it afforded opportunity to make analysis of the conditions for business as reflected by those in position to make accurate estimate. The prevailing opinion was that the coming year ought to be the best the company has yet experienced, and that with the selling force better organized and with more intimate knowledge of the market and the requirements of the people the sales should be materially increased.

The evening of the concluding day a banquet was given by the company at the Hotel Cadillac, which was an occasion of much pleasure. The menu was stated in representations of engineers' blue prints, bearing the Federal seal in gold, and on the title page was the inscription "Bill of Material and Specifications of 1914 Model Federal Ginger Dinner, All Material to Be f. o. b., Hotel Cadillac. Deliveries: 7:30, 1-21-14." With this was printed parodies of well known popular music, all of which were adaptations to extol the qualities of the Federal machines.

In connection with the dinner was an entertainment, a feature of which was a one-act play written by Kirk B. Alexander, entitled "Pass It Along", which was stated to be "A Realistic Melodrama of the Motor

Truck Business in One Frightfully Frank Act." The skit was a burlesque of the relations of factory officials and dealers, and the men who held the jobs assumed the characters. Following the pleasures of the evening the National Federal Dealers' Association was organized with Allan Baker, St. Louis, Mo., president; William L. Hughson, San Francisco, vice president; C. T. Chenevert, assistant sales manager with headquarters at New York City, secretary, and H. S. Dunlavey, Chicago, treasurer. The specific purpose of the association is to foster the spirit of co-operation of the selling force, and to promote the service given to owners of Federal machines.

LOCATED IN NEW FACTORY.

The Morton Truck and Tractor Company, Harrisburg, Penn., has purchased the plant once operated by the Model Typewriter Company in 19th street, that city, a three-story structure, and will shortly begin the manufacture there of the Morton trucks and tractors. The company has increased its capital from \$250,000 to \$300,000.

WILL BUILD FIRE APPARATUS.

The Haney Rescue Apparatus Company has been incorporated at Tampa, Fla., with authorized capital of \$2,000,000. The purpose is to acquire the interests of the Haney Fire Apparatus Company, Stockton, Cal., and build and equip a factory at Tampa at a cost of \$150,000 to \$200,000, to manufacture automobiles, motor trucks, pumps and fire elevators.

ANOTHER GARFORD STATION.

The R. & L. Company, eastern distributor of Garford trucks and Willys Utility wagons, which now has two service stations in New York City, has planned a third which will be erected at Atlantic and New York avenues, Brooklyn, close to the Brooklyn branch. The building will be 100 by 60 feet, of fire-proof construction, without posts, and designed purposely for the service. It will be open constantly to afford service to Brooklyn and Long Island residents, will be stocked with parts for all trucks and pleasure cars, and mechanics will be on duty at all times. Besides the two stations at 64th street and West End avenue in Manhattan and at 150th street and Gerard avenue in the Bronx, the company has a station at Newark, N. J., the latter for the convenience of the New Jersey people.

The "Ginger" Dinner of the Salesmen and Officials of the Federal Motor Truck Company, Held at the Hotel Cadillac, Detroit, Mich.

THE INITIAL CHARACTERISTICS OF THE PHILADELPHIA THIN PLATE BATTERY.

By James M. Skinner, Engineer of the Philadelphia Storage Battery Company.

UNTIL recent times most batteries have been sold as a finished product, assembled, developed and ready for use. Of late the tendency has been in another direction, and today many large battery users are buying from the battery companies merely the knocked down parts—plates or groups, separators, etc., and are doing their own assembling and developing.

Although the ordinary battery instruction book published by the Philadelphia Storage Battery Company gives full directions as to the proper developing procedure, it does not go far into the whys and wherefores, nor does it give any explanation of the initial capacity characteristics which are sometimes very puzzling to the user. It is the purpose of this article to dwell particularly on these omitted points. The article is centred upon the Philadelphia thin plate for two reasons, first because the Philadelphia thin plate is the standard of all the batteries which can be assembled by the user, and second, because the tests, upon which the statements given are based, were made upon Philadelphia thin plates.

Initial Charge.

As a general proposition the more plates which are put into a given size jar, the longer it will be necessary to continue the initial charge. At first glance this appears to conflict with the well known fact that thin plate batteries have a higher efficiency than thicker types. But it must be remembered that at the beginning of initial charge the plates are in a very different condition than at the beginning of an ordinary service charge. At the beginning of initial charge the positives are fairly free of sulphate, while the negatives are very heavily sulphated, particularly on the surface, having been purposely put into this condition to avoid heating and so that they may better withstand the knocks and bumps of shipping. The depth of the hard surface sulphate is about the same regardless of the thickness of the plates. Furthermore, the wood separators are not yet thoroughly opened up. The purpose of the initial charge is to complete the charge on the positives, to soften up the hard negative surfaces, to bring the wood separators into porous normal working condition and to balance things up generally. Now the more plates in a given size jar the more hard negative surfaces there are to soften and the more sep-

arators to open up. Therefore the more plates in a given jar the longer the initial charge required.

A high current rate cannot be used on initial charge for several reasons. First, the positives are nearly charged to begin with and a high current rate would cause them to gas excessively, and would tend toward heating. Second, the wood separators are of high resistance and forcing heavy current through them would surely cause heating. The proper rate to use averages 30 per cent. of the normal catalogue discharge rate. This figure is selected because a battery will usually take it for the entire initial charge without heating. If the temperature rises above 100 degrees, however, the rate must be lowered.

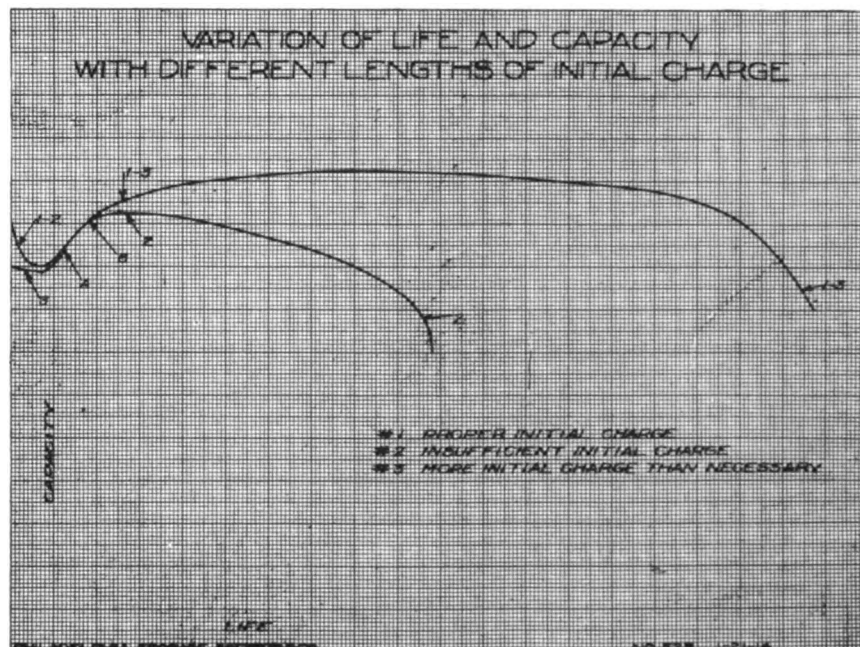

Fig. 1.

Although it is desirable to keep gassing down to a minimum on initial charge, just as on any other charge, it cannot be so entirely eliminated on initial charge as on ordinary service charges, because as mentioned above the positives are fairly free of sulphate to begin with and will therefore start to gas long before the heavily sulphated negatives are reduced. This unbalanced initial condition of the plates is unavoidable, but its effect can be nullified by keeping the rate low enough to avoid overly hard gassing of the positives.

The time required for initial charge with Philadelphia thin plates is about six to seven days at 30 per cent. of the normal discharge rate, or in ampere-hour input about seven to eight times the rated ampere-hour capacity. If the current rate is lowered the

Fig. 2.

duration must be proportionately increased. In the great majority of cases an initial charge continued until the ampere-hour input is from seven to eight times the rated ampere-hour capacity will be entirely sufficient, but as additional checks the following points may be noted:

1. The initial charge is never complete as long as the specific gravity of the acid is rising, and may not be quite complete when it does stop rising, because the increase due to the acid coming out of the plates may be balanced by the amount being carried off by the gas.

2. The initial charge is not usually complete until the voltage of each individual cell is 2.60 or above at a current rate 30 per cent. of the normal discharge rate.

3. The initial charge is not usually complete until the positive cadmium reading is 2.39 or above at a current rate 30 per cent. of the normal discharge rate.

4. The initial charge is not usually complete as long as the separators are giving off foam. The foam is the result of an action between the wood, lead peroxide and sulphuric acid and is carried up to the top of the cell by the gas generated in the plates. As long as it continues it indicates that the separators are not yet opened up to the proper extent.

If the initial charge is continued longer than necessary it is possible that a slightly lower capacity will be obtained on the first discharge; but this effect is only temporary and is attended with no danger to the life of the plates. It is due to the fact that the thin surface film of peroxide on the positives has been washed off to a greater extent by the longer continued gassing. On the other hand, if the initial charge is unduly shortened, there is danger that the negatives, not having been given the proper start, may cause trouble later on in the life of the battery, even though, due to their normal excess initial capacity over the positives,

they may not cause any decrease in the initial capacity of the battery. The theory here is as follows:

When negatives are not fully charged on the initial charge there remains in them some unreduced lead sulphate. This sulphate is rather dense and large particled to begin with, and being in contact with sulphuric acid tends to constantly dissolve and redeposit, and thus to become even harder and of still larger particles. The presence of this sulphate in the plate tends to clog the pores and to prevent normal acid diffusion. In addition, each large particle seems to act as a magnet, attracting to it on each discharge a small quantity of the normal sulphate then produced and adding it to itself, thus further tending to block up the pores. It is easy to see that the consequence will be a steady decrease

in negative capacity, with a possibility of the sulphate becoming so hard that even long continued overcharging cannot put it into good condition. Happily the only precaution necessary to entirely eliminate any chance of such negative trouble is a thorough first charge, which will entirely rid the negatives of their initial sulphate.

Fig. 1 shows three life curves. No. 1 is a battery with the correct initial charge. No. 2 has been given too little charge, No. 3 has been given more than necessary. It will be noted that 1 and 2 start together. The negatives in 2, although undercharged, have still enough capacity to give as much as the positives and nothing is noticed on the first few discharges. No. 3 starts off somewhat lower than either of the others. The negatives are in perfectly good shape, but their excess capacity does not have a chance to show because the positives come down first. Thus the positives are limiting the capacity in all three cases and the capacity is lower in 3 simply because the charge has been continued for say 10 days instead of seven, and the soft surface film of peroxide has been washed off to a greater extent. But notice at A that all three are giving the same capacity, and that 1 and 2 are below their initial capacity. The surface films of peroxide on 1 and 2 have been softened and washed off by the working of the battery, and all the positive plates are now in identical condition. Between A and B the surfaces of the positives are gradually softening, due to the charging and discharging, and the capacity is increasing, all three to the same extent. But at B, 2 starts to fall back. Why? Because the negatives are showing the effect of the initial undercharge, are losing capacity, and are now going down before the positives and limiting the capacity of the cell. The rest of the figure is self-explanatory. To sum up, any low capacity from too much first charge is temporary and has no appreciable effect on life, but too little first

arge may materially shorten the life by causing an
mate shortage in negative capacity. Therefore, in
e of doubt, play it safe.

Hard and Soft Positives.

Fig. 1 dealt principally with negatives. Fig. 2 con-
sists itself with two widely different kinds of positive
es, those with soft paste and those with hard paste.
t positives at the start look fine. They give high
ial capacity and quickly rise even higher, and after
r or five months of service look better than ever.
about that time, depending on just how soft the
te was, they begin to show signs of going back
then quickly go down. Hard positives on the other
d are sometimes very difficult to get along with
ally. The capacity is good on the first discharge,
then starts to fall off and may decrease a little for
next two to five cycles. It may then hold steady
a few cycles and give no indication of ever increas-

But after a maximum of about a dozen cycles it
ts to climb and goes steadily upward until, just
at the time that the soft plate capacity begins to
down the capacity of the hard plates is beginning
ach its maximum. The essential difference is this,
soft plates work throughout their entire depth,
the whole mass of material grows soft and mushy
ice, falling quickly to the bottom as sediment; the
plates work principally on a softened surface
which, as it sloughs off, is constantly reformed
the hard material underneath. The capacity on
first few discharges is likely to decrease because
nitial film is washing off and the hard underneath
erial is not softening quite as fast. However, the
nd film will surely form if charging and discharg-
be persisted in, and once it properly starts the ca-
y will increase in many cases to 20 per cent. above
l capacity.

ow, all this is in one sense very unfortunate. Most
ries are given their service test after one or two
loping discharges, and if they con-
hard positive plates their capacity
e time of test is at the lowest figure
it ever reaches, and perhaps consid-
y below rating. Naturally the sus-
ns of the purchaser are aroused at
—his first thought is that he has
old of a very poor or very much
ated battery, he promptly registers
nphatic kick with the battery com-
, and in the meantime takes the
ry out of service. Now what the
ry needs is work, and the harder
work the better. Charging alone
never raise the capacity, because
as keeps washing off the surface
as fast as it is formed. Discharg-
needed in addition. The sulphate
ed during the discharge, especially
e a long discharge, spreads the ma-
apart and paves the way for
pores when it is removed on

the next charge, thus rendering easier the formation
of a deeper surface film. To raise the capacity, the
longer the discharge the better, providing that it is
compensated for by sufficient charge to remove all the
sulphate formed. There is one precaution necessary
however—do not at any time allow any cells to re-
verse.

Method of Procedure with Hard Paste Plates.

To incorporate the above in the form of definite
directions: If it is possible to get along with low ca-
pacity for a short time, put the battery into service,
work it hard, charge it well, and the capacity in two
or three weeks will have risen to rating or above. If
on the other hand it is necessary to have full rated ca-
pacity before putting the battery into service the fol-
lowing procedure will hasten matters a great deal:
Take an ordinary discharge and when most of the
cells have come down to 1.70 volts, cut the current
rate in two and continue the discharge until about
half the cells have reached zero or thereabouts. If a
few cells reach zero long before the others, prevent
them from reversing by connecting a wire across their
straps. Following this "run-down" give the battery
a full charge and discharge again. The capacity will
usually be greater than before. If it is still low an-
other "run-down" may be taken and the capacity on
subsequent discharges is almost sure to be above rat-
ing. The above procedure, providing that no cells are
reversed, will have no appreciable effect on the life
of the battery unless repeated too often. Three times
is a safe maximum.

A more thorough investigation of the effects of
this "draining" or "run-down" procedure may be in
order here. The net result of a run-down is to deepen
the surface film. If a run-down is taken following the
first discharge the capacity on the second discharge,
assuming of course a full charge between, will always
be higher than the capacity without a run-down hav-

Fig. 3.

ing been taken, but it may still be below the initial capacity. Whether it is above or below depends merely upon whether the film has been deepened to a greater extent than it has been washed off by the working of the battery. On this basis it is easy to see that hard gassing on the second charge might wash off so much of the film that there would be almost no gain in capacity due to the run-down. When the run-down process has been employed and the battery thereby worked up to a little above rating, the capacity will usually fall off a little on the next few discharges and then start to climb. It will not, however, fall as low as it would have without the run-downs and it will start to rise more quickly.

Fig. 3 shows the effect of two run-downs on the capacity of the early discharges. Notice that while the capacity on the second discharge is less than that on the first, there is quite a substantial gain over the capacity obtained without the run-down. On the third discharge the capacity drops below the second, but would never go as low as the lower curve. Where possible it would be well to stop here and to allow the capacity to work up normally in service. Note the effect of the second run-down in raising the capacity above rating, but notice that there is still a slight drop on the discharges following the run-down, indicating that the run-down film has washed off slightly faster than it has been reformed. Finally notice that after about a dozen discharges both batteries are giving the same capacity. In other words, the two run-downs, while effective in increasing the initial capacity, have no effect on the ultimate capacity. From this it may be seen that there is no use in spending the time and current to run a battery down even once, if it can be put into service and made to perform useful work while the capacity is increasing. It is only in cases when high initial capacity is absolutely required that run-downs are economical. The capacity will always come up without them if the battery is put to work.

"Run-Downs" Not a Universal Cure-All.

It must not be assumed that run-downs are a universal cure-all. They are applicable only to new hard plate batteries which are showing low capacity even after full charges and they must be carried out with common sense and careful attention and not repeated more than twice. They should not be used unless the capacity is considerably below rating and it is better where possible to let the capacity work up more naturally under ordinary service discharges and full charges.

It is hoped that the foregoing may be helpful toward a better understanding of the initial characteristics of the thin plate and particularly of the hard positive thin plate. The gist of the matter is this—what hard, low capacity plates need is work, and if it is given them, either in service or by run-downs on the bench, the capacity will surely rise above rating and often far above, and that, furthermore, any low initial capacity obtained will always be compensated for many times over by the longer life obtained.

TO LOCATE AT MOUNT VERNON.

Ward Motor Vehicle Company Will Remove Plant from New York.

The Ward Motor Vehicle Company, now located in a factory at Concord avenue and 144th street, Bronx, New York City, has purchased a site in South Fulton avenue in Mount Vernon, N. Y., on which the company purposes to build a manufacturing plant, probably in the spring. The Ward Motor Vehicle Company is one of the old concerns of the electric motor vehicle industry. It was organized primarily to construct electric wagons for the Ward-Corby Company, a baking company that has bread bakeries in a considerable number of cities, and for a number of years its business was practically confined to the production of a comparatively light type of wagon that could be used for the delivery of bread from the bakeries to customers.

The electric vehicle was favored because of the absence of odor of any kind and the necessity of utilizing machines that would not in any way cause deterioration of the bread. A standard type was adopted as suited to the particular work and until about two years ago the company produced these, a comparatively small number being built to order. The company's officers then decided to construct vehicles commercially, and a standard design was adopted and this chassis was built, and is now produced, in 2000, 4000, 6000 and 8000-pound capacities. In practise these machines were efficient and economical and afforded excellent results.

The Ward-Corby Company has in Brooklyn, where its New York factory is located, one of the largest installations of electric vehicles in the world, there being about 160 of them in daily operation. Because of the number of Ward machines in service its maintenance department is of considerable size.

The intention of the company is stated to be the erection of a factory that will have ample machine and hand tool equipment and facilities for producing several hundred vehicles a year. The plant will have a spur track from the Westchester branch of the New Haven railroad and a dock on East Chester creek, where small cargoes of fuel and material can be received or finished machines shipped. Work on the buildings will be begun in the spring and hurried to completion. The company will employ several hundred hands when working to capacity. While no announcement has been made it is believed that considerable attention will be devoted to the production of pleasure cars.

With capital of \$100,000 the Electromobile Company has been organized at St. Louis, Mo., under the law of Missouri, by Sanford J. Bernheimer and others, to build industrial trucks for internal freight work.

S. A. E. SUMMER MEETING.

The committee in charge of the arrangements for the summer meeting of the Society of Automobile Engineers, which will take place at Cape May, N. J., June 27, has made material progress, and the purpose is to make the occasion one of unusual interest to the members and their families. The committee has engaged the entire hotel, which has 350 rooms, for the period the meeting will be held, and all of the means of amusement, the privileges of the bathing beach, golf links, tennis courts and the like will be reserved exclusively for the benefit of the members of the society and their families.

The professional sessions of the society will be of decided interest, for special papers will be read and discussion will take place, but in addition there will be entertainment in the open air each afternoon and at the hotel in the evening. Among the features will be a moving picture lecture on the parts of Europe that will be visited by the society during the projected tour abroad next autumn. Special trains will be run from Philadelphia to Cape May for the transportation of the members, and special rates have been obtained for the accommodation of the visitors. The mid-summer banquet will be an occasion of unusual importance.

PALMER-MOORE OFFICERS.

The stockholders of the Palmer-Moore Company, New York, N. Y., at the annual meeting of that concern, elected these directors for the ensuing year: T. G. Meacham, T. W. Meacham, J. F. S. Meacham, C. L. Palmer, A. N. Palmer, Edward Moore and R. R. Scott. The directors organized as follows: President, T. G. Meacham; vice president, T. W. Meacham; secretary-treasurer, C. L. Palmer. The reports of the company showed that the concern was in a very satisfactory condition.

Clifford B. Myers, who was general manager for the Swinehart Tire & Rubber Company, Akron, O., resigned that position and after a rest will probably associate himself with a concern engaged in a similar line of production. Mr. Myers was for a considerable period associated with the Diamond Rubber Company.

The laboratory and testing department of the American Bronze Company, Berwyn, Penn., is now in charge of Leighton Dunning, who was a member of the engineering department of the General Electric Company, Schenectady, N. Y.

The appointment of H. H. Edge, superintendent, to the position of factory manager, is announced by the Automobile Company of America, Bridgeport, Conn. E. F. Russell, resigned.

DRY GOODS DELIVERY SERVICE.**National Association Creates Department to Promote Transportation Efficiency.**

A substantial evidence of the keen interest of business men in transportation efficiency is the fact that the National Dry Goods Association, which has membership composed of firms in all sections of the United States, has organized a department devoted to the promotion of the haulage services of the members. The association has for years carried on work that has been of large practical benefit to the members, and as this has been developed departments have been created and placed in charge of men of experience and recognized capacity, the services of the divisions being at the command of those who sought advice that they might improve conditions so far as their businesses were concerned.

The association has headquarters in New York City, and there the organization is centred, the different departments maintaining activities that may be required to meet the demands of the members. A considerable proportion of the firms having membership have delivery services, and these are proportionate to the needs. Some have motor equipped departments, developed by years of experience, but many are beginning to consider changes from animal vehicles and seek to obtain through the association the information that they might obtain by audits of books or by the maintenance of systems of records.

But the majority of requests are for facts that are required immediately, and delay would be a matter of material consequence. While it may not be practical to ask local competitors for this detail the association can from records supply much information that will be of decided benefit, and any member is justified in asking for whatever will serve his purpose. The frequency of these requests and the widespread interest of the members prompted the directors to create the department, and all having membership have been asked to contribute facts for the records. With the accumulation of these data the association placed at the head of the bureau J. M. VanHarlingen, who has been known as a transportation engineer, having had considerable experience with a large manufacturer of trucks, and he is now at work systematizing the records with a view of affording the members a standard character of information that may be available at any time. The policy of the association is to broaden the scope of the department and strengthen its efficiency wherever this may be done.

The Perfection Spring Company, Cleveland, O., has established a service station at Euclid avenue and 63rd street in that city, and will, it is stated, extend this department by the establishment of similar stations in New York City and Chicago.

STANDARD CHARGING PLUG.

Two Sizes, Outside Contact Positive, Approved by Electric Vehicle Association.

For the benefit of all who may be in any way interested the Electric Vehicle Association of America is distributing a specification sheet showing a detail sketch of the standards for charging plugs recently approved by the organization. Those familiar with electric vehicles understand the value of this information, but for the benefit of those who may not be informed the explanation is made that the charging plug is the terminal of the cable lead from the line carrying the current, and is a permanent fixture. All vehicles are fitted with a receptacle, so-called, which is connected with the wiring of the battery and the operation of charging is practically automatic when the charging plug is fitted into the receptacle.

But efficient transmission of energy is only practical where the contacts are good and the charging plug fits the receptacle. Until the present time charging plugs and receptacles have not been uniform. A charging cable and plug is not generally carried, and when in the event of emergency a supplementary charge is necessary if the plugs of the cables will not fit, or fit imperfectly, the receptacles of the vehicle, a situation results that is exasperating, if not serious, and when applied to a service machine may be discouraging.

A standardization committee of the association carefully considered the problem, and in communicating with manufacturers of vehicles found that out of 20 replies 13 were using a concentric type plug. Of this 13 nine made the centre terminal negative, and five manufacturers made the centre terminal positive. In view of the facts ascertained the committee recommended that the association approve a plug with the outside terminal positive and the inside negative.

The specification sheet shows that the committee recommends two standard sizes, the smaller of 50 amperes capacity for pleasure cars, and the larger of 150 amperes capacity for trucks, either to have a 50 per

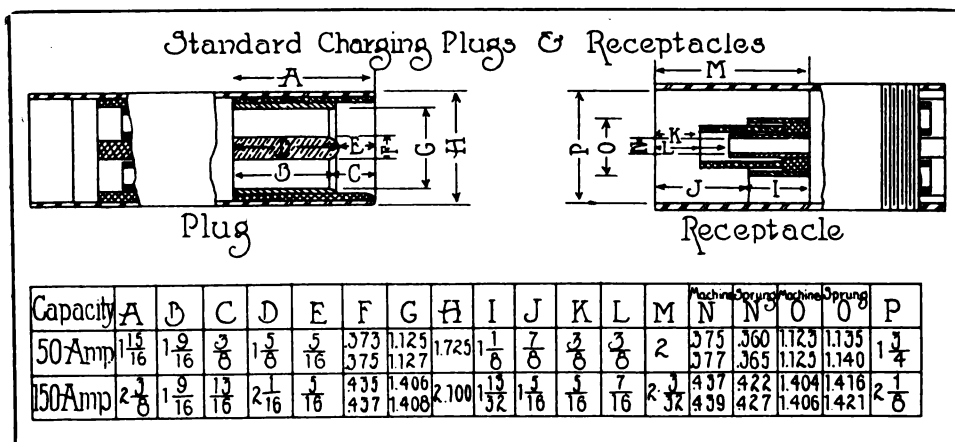

cent. overload capacity. The detail dimensions are set forth in a tabulation. The National Board of Fire Underwriters has approved plugs of the dimensions given. The association's committee has recommended that the terminals should be large enough to receive cable having a rating, according to the Underwriters' Code Table B, at least equal to the normal rating of the plugs, and that the terminals should be marked plus and minus to correspond to the polarity of the plugs. The committee is now distributing these sheets to all persons interested, to manufacturers, owners and charging stations and garages urging the prompt adoption of the standardized plugs and receptacles, and the change of polarity, both on old and new vehicles, and charging equipment, to bring about a desired uniformity. The belief is, that when the standard has been adopted and the change made as suggested, electric vehicles can be charged anywhere that electric current is made, and all delays or complications will be eliminated.

DETROIT OWNERS PROTEST.

The common council of Detroit now has before it the petition of 82 owners of motor wagons and trucks, residents of that city, who seek to bring about the repeal of the ordinance now effective, that requires the use of fenders on service vehicles. The protestants set forth that they have been unable to find fender equipment that will afford the protection required, and for this reason are unable to comply with the regulation, although they are willing to purchase fenders and do not wish to be understood as offering the petition on the basis of expense.

AS AMERICANS SAW THEM.

The members of the British Institution of Automobile Engineers have received from the Society of Automobile Engineers a unique remembrance, which will no doubt have a prominent place in the library of the organization, this being in the form of a leather bound volume that includes hundreds of press clippings relating to the visit of the English association to America late last spring. The clippings are of every character, and chronologically arranged describe the tour of the visitors, the entertainment afforded industrially, scientifically and socially, and incidentally reflect some interesting observations. The book was sent so that it was received during the holidays, being sent by the general committee of arrangements of the S. A. E.

The Detail Drawings and Dimensions of the Charging Plugs and Receptacles Approved and the Use Recommended by the Electric Vehicle Association.

MOTOR VEHICLE USE BY CHICAGOANS.

AN ANALYSIS of the records of the vehicle department of the office of the Chicago city tax collector to Dec. 24, 1913, shows that the motor vehicles have increased almost beyond belief during a period of three years and seven months, and that the number of horse vehicles has materially decreased. This is one of the first statements that has been made that demonstrates the relative use of automobile carriages, wagons and trucks and those drawn by animals. The public has generally understood how great is the demand for pleasure cars, but the supposition has been that wagons and trucks were comparatively few in number.

The city has taxed all classes of vehicles since May 1, 1910, and its record can be regarded as authentic. Prior to May 1, 1912, pleasure cars were taxed on seating capacity, and after that date on horsepower. For convenience in making comparison the record will be referred to by years, but the last period will be understood as covering seven months and 24 days, and the figures stated for this term will probably be considerably increased before the end of the full year. The number of all types of vehicles taxed for each period was as follows:

	1910-11	1911-12	1912-13	1913—
Horse vehicles.....	58,114	55,785	55,502	54,037
Pleasure cars.....	9,963	11,876	16,857	21,332
Service wagons.....	799	1,578	2,835	3,964
Demonstrating cars.....	326	490	593	614

The classification of these vehicles is of especial interest, and shows the following:

	1910-11	1911-12	1912-13	1913—
Single-horse vehicle.....	40,109	38,694	38,429	38,019
Two-horse vehicle.....	17,640	16,771	16,728	15,745
Three-horse vehicle.....	331	290	325	256
Four-horse vehicle.....	34	30	20	17
Motorcycles.....	1,838	2,778	4,112	4,819
Pleasure cars.....	9,963	11,876	16,857	21,332
Motor wagons and trucks....	799	1,578	2,835	3,964

The business of the city undoubtedly increased during the period covered by these figures, but the relative decrease of horse vehicles is shown by the following:

	1911-12	1912-13	1913—	Total
Single-horse vehicle.....	1,415	265	410	1,415
Two-horse vehicle.....	869	43	983	1,895
Three-horse vehicle.....	41	•	69	110
Four-horse vehicle.....	4	10	3	17
Total.....	2,329	283	1,465	4,112

*Increased 35. †Increase of 35 included in this tabulation.

Just what proportion of the single-horse vehicles were used for business purposes is uncertain, but it is reasonable to assume that a considerable part of the total decrease in single animal conveyances is now represented by motor delivery wagons. This is borne out by the following division of industrial machines.

	1910-11	1911-12	1912-13	1913—
Capacity				
Up to 2000 pounds.....	436	922	1,680	2,297
More than 2000 pounds.....	363	656	1,155	1,667
Total.....	799	1,578	2,835	3,964

During the period dealt with the increase of service motor wagons has been 396 per cent., while the in-

crease of pleasure vehicles has been 114 per cent., and the decrease of horse drawn conveyances has been approximately 7.5 per cent. One will note that the greatest loss has been of the two-horse teams, a very large proportion of which is used for haulage purposes, and there is practically the same shrinkage with reference to three-horse hitches, though the number is surprisingly small for a city the size of Chicago.

The tabulations show that more than 30 per cent. of all vehicles in use in Chicago are automobiles, and while it may be assumed the passenger cars are used practically to the exclusion of animals for pleasure and recreation, one can also assume that more than 90 per cent. of the animal vehicles taxed are used for service. The gain of wagons and trucks has been marked, and it is probable that the rapid increase will continue. During the unfinished fourth period the total number of taxable machines has increased more than 1000, and with this ratio of gain there is every reason to believe that the aggregate at the end of 1914 will approximate 5500 at least.

WAGENHALS TO BUILD ELECTRIC.

The Wagenhals Motor Car Company, Detroit, Mich., which has for a considerable length of time built a three-wheeled vehicle driven by a four-cylinder engine designed for light delivery purposes, has developed an electric machine of much the same type that is now being tested. The purpose is to perfect the vehicle and to produce it commercially as soon as experiments have established its construction and efficiency.

The electric machine is driven by a single rear wheel, steered by the two forward wheels, and the power is provided by a General Electric Company's motor and a 24-cell Exide battery. The capacity of the machine is 600 pounds. The mileage will depend upon road conditions, but where the highways are normal the machine is expected to make 45 miles on a single battery charge.

With capital of \$1,000,000 the A & T Storage Battery Company has been incorporated in New York City by W. C. Albers, A. L. Kull, D. B. Nally and John Splitdorf. The plans of the incorporators have not as yet been made public.

The United States Ball Bearing Manufacturing Company, Oak Park, Ill., is now marketing through its own selling organization, which is established in the general offices of the company at the factory.

The Packard Motor Car Company, following the holiday season, increased its force of workers to the normal number, several hundred men having been idle for several weeks.

THE WAUKESHA MODEL O MOTORS.

TO MEET the demand of motor truck manufacturers who prefer to use engines that have been developed and specialized rather than build their own, the Waukesha Motor Company, Waukesha, Wis., has begun the production of a heavy duty type that is designed for installation in trucks and wagons, and is suited for industrial and stationary service. The company maintains that the engine design has been very carefully worked out and that in experimental work and tests it has been found to be extremely economical and enduring. These motors are now produced commercially with the assurance of the maker that they are especially adapted for the purposes stated.

The motor is built in five sizes and it can be furnished either as the engine complete or the unit power plant, comprising the clutch, transmission gearset and pedals and control levers. The motor is known as the model O, and it can be furnished in these sizes: Cylinder bore of 3.25 inches and stroke of five inches; cylinder bore of 4.25 inches and stroke of 5.75 inches; cylinder bore of 4.25 inches and stroke of 6.75 inches; cylinder bore of 4.5 inches and stroke of 6.75 inches; cylinder bore of 4.75 inches and stroke of 6.75 inches.

For the purposes of description the 3.75-inch cylinder bore and 5.75-inch stroke will be taken, but in all respects other than proportions the motors are identical. The rating of this engine, which is regarded by the maker as being sufficiently powerful for 2000, 4000, 5000 and 6000-pound machines, by the S. A. E. formula, is 16.9 horsepower, but it will develop much greater power than this, and 25 horsepower would not be excessive. By the same formula the other sizes are rated at 28.9, 32.4 and 36.1 horsepower, but the long stroke insures that these ratings will be materially exceeded in practise.

The maker claims that in conforming to the heavy duty practise of the company the motors have these distinctive qualities: Long bearings of large area,

chrome nickel crankshaft, small bore and long stroke, the "Waukesha" patented non-hunting and self-lubricating governor, great accessibility to all parts, and such disposition of the fuel charge as to afford large economy of operation.

The motor is a conventional four-cylinder, water-cooled, L head type with cylinder units cast in pairs with the water jackets integral. The cylinders are cast of a semi-steel mixture of a very close grain and the water jackets are generous in size, large cover plates carrying the water outlet manifolds. The cylinders are annealed after casting and are then rough bored and reamed, after which they are aged to insure against the development of casting strains and cracks. Following the ageing the units are ground to accurate dimensions. During the processes of finishing the cylinder is tested five times to detect possible imperfections. The pistons are cast of the same metal as the cylinders and these are turned to size and ground to the cylinder dimensions. Each piston carries two rings of the same metal as the piston, of special design, and ground and fitted with care to secure good compression. The pistons are "relieved" in the centres of the walls and three oil grooves are made in the skirt of each piston to secure even and thorough distribution of the lubricant on the cylinder and piston walls. The piston lugs are bushed to take the wear of the wristpins, which oscillate in the lugs.

The crankcase is cast of an aluminum alloy and is designed with heavy walls and ribs in the sections where stresses are imposed. The base of the case contains the oil reservoir. The supporting arms and the brackets for the magneto and the pump shaft are cast integral with the case. The crankshaft of chrome nickel steel is heat treated and has a tensile strength of 140,000 pounds and an elastic limit of 122,000 pounds to the square inch, and a shore hardness of 40-45. The shaft is so hard that it will not cut or score under extremely severe conditions of use. The shaft is carried on three bearings, the forward being 2.75 inches length, the centre 3.25 inches length and the rear 3.75 inches length, this giving a total length of 10 inches of bearing surface. At the rear end is a large flange to which the flywheel is coupled by six .5-inch bolts. The shaft is two inches diameter at the main and connecting rod bearings and the crankpins are two inches length.

The connecting rods are 40 carbon steel drop forgings, heat treated, with a split clamp small end and a four-bolt cap at the crankpin end; the caps are retained by heat treated bolts of chrome nickel steel .21875 inch diameter, these being fitted with a special castellated nut to insure effective adjustment. The connecting rod bearings are specially designed of Fahrig metal with reinforced backs to prevent distortion. These bearings are retained by brass taper headed screws and keyed on by heavy shims, adjustment being afforded

Left or Valve Side of the Waukesha Model O Motor.

series of thinner shims. The rods are reinforced to have great rigidity at the big ends. The wristpins are chrome nickel steel tube with walls .15625 inch thickness, case hardened and ground. These pins have a total bearing surface of 2.5 square inches.

The camshaft is a 20 carbon steel drop forging with the cams cut integral and the cams are ground to a master shaft. The shaft is case hardened throughout.

The valve tappets or pushrods are a roller type, and are 1.125 inches diameter. They are bored to form sleeves with walls .0625 inch thickness and are case hardened and ground. The pin is of tool steel and this and the roller are case hardened and ground, as is the adjusting screw, which is locked with a soft steel nut. The rollers and pins may be renewed when worn. The guides for the rods are of semi-steel and are carefully reamed and grooved to insure effective lubrication. These guides have a total bearing area on the pushrods of 3.25 square inches. The valves are made with alloy steel heads, are hardened and are made with long shallow recesses into which taper washers are fitted which lock the springs when placed. The valves have very large fillets, which strengthen the heads and prevent warping, and at the same time afford easy passage for the fuel gas.

The motor is lubricated by the Waukesha force feed and splash system, which has been proven in long practise to be very efficient. The oil is contained in a reservoir in the base of the crankcase, and it is drawn from this through the filter by a gear driven pump and forced through tube to the timing gears, lubricating all the bearings. The oil is fed into the base of the crankcase where it is collected in pits or pockets into which the big ends of the connecting rods, fitted with scoops, sweep at each revolution. These pockets are very deep and have no overflows. The splash carries oil to pockets that feed to the crankshaft and camshaft bearings, and the valve tappets, the tappet guides, the cylinders, pistons and wristpins and wristpin bearings. The drainage is carried into the pump and is constantly circulated. The system is so designed that the flow of lubricant is equalized and there is always a sufficient volume of oil to afford ample lubrication, and a correct level at any angle the engine can be operated.

The motor is governed by a governor of the fly ball type, which is so constructed that the spring that establishes the speed binds all the moving parts and insures simultaneous action, which, with the dash pot, eliminates all "hunting". In addition wear of the governor has a tendency to reduce motor speed. All parts of the governor are not accessible to the driver, which is enclosed and lubricated from the engine oiling system. When desired a certain speed can be established and the governor sealed. The governor can be used as a maximum speed governor or it can be set for handling a specific load. All these distinctive features are covered by patents.

The motor will deliver its maximum torque at 600 revolutions a minute, so that it cannot be driven to a speed that would be damaging. It is claimed by the

maker that during the period of experimentation, covering many months, three of these motors in two-ton trucks averaged more than eight miles to the gallon of fuel, or a total of more than 60 ton-miles to the gallon of gasoline.

GOODYEAR COMPANY'S BIG YEAR.

The Goodyear Tire & Rubber Company during the fiscal year of 1913 did a total business of approximately \$32,500,000, the total sales amounting to \$29,000,000 and the profit to \$2,041,000. During the year a 33 per cent. dividend was paid on common stock amounting to \$603,102. The officers of the company were re-elected as follows: President, F. A. Seiberling; vice president, C. E. Seiberling; secretary, G. M. Stadelman; treasurer, F. H. Adams.

Two Federal trucks have been recently sold to the Mexican government that are supposed to be used in connection with the field activities of the Mexican army. As two Federal machines are used for "gun-running" by the constitutionalists, so far as can be judged the chances are even.

A factory branch has been opened by the Chicago Pneumatic Tool Company, maker of Little Giant delivery wagons, at 234 14th street, N. W., Washington, D. C., which is under the management of G. C. Stevens.

Under Illinois law the Stegeman Motor Truck Company has been incorporated at Chicago, Ill., with capital of \$10,000 by D. H. Bucklan, E. E. Burkland and R. C. Flodin.

The Kissel Motor Car Company, Hartford, Wis., has appointed Clifford E. Golder manager of the truck department of the Milwaukee, Wis., branch.

Right or Pump and Magneto Side of Waukesha Model O Motor.

REAL VALUE OF QUICK LOAD HANDLING.

A MOTOR vehicle is productive of economy in proportion to the direct ratio to the method of use. The machine need not be overloaded or driven at excessive speed, but the principal purpose is to utilize it every minute that is practical. No manufacturer would believe that he could produce successfully unless his machines were in operation, and if these were operated continuously the best results would be obtained. The same principle can be applied to vehicular haulage, and where facilities have been provided that will insure quick loading and unloading trucks or wagons can be used with remarkable saving as compared with the use of animals.

An illustration of the possibilities, where practical thought is given to methods, and where the hauls are exceedingly short, is that of H. L. Beauvais of Earville, O., who is engaged in the haulage of sand and gravel used for the making of concrete for the construction of a dam in the Cuyahoga river near that place.

A water works system for the city of Akron, O., is being constructed, and the dam is to form the lower end of a large reservoir. When finished a considerable part of the river bottom will be flooded and that the dam shall be permanent and enduring concrete is the material principally used in its construction. Beauvais has a contract for supplying the sand and gravel from a large bed he controls a trifle more than a mile from the site of the dam. An enormous quantity of material will be required for the work and the sand and gravel must be transported from the bed to the dam. The concrete is mixed and made ready as near the dam as is possible and it is necessary that a sufficient quantity of gravel and sand be furnished that the work may be carried on without interruption.

Mr. Beauvais bought a Peerless five-ton truck to haul the material from the bed, and to realize the fullest value of the machine a power dumping body was installed on the chassis. The proposition was to make this truck do all the work that was necessary, and to obtain the fullest utility of the vehicle it must be kept

in operation with the least possible loss of time. Overloading was regarded as unnecessary and the quick discharging body was of only partial value unless it could be loaded and unloaded rapidly.

A steam shovel was installed at the gravel pit, this being a machine that operates a clam shell bucket that will lift the material and deposit it within the radius of the derrick arm. The shovel is located in an excavation and the truck can be driven along the edge of this and loaded at any convenient point. As the excavating progresses the shovel can be moved and practically the same condition for loading continued. The truck will carry four yards, weighing about 2850 pounds to the yard and about 11,400 pounds to the load a trip.

The distance from the gravel bank to the dam is approximately 1.1 miles, the highway being a comparatively poor road that descends from a bank of considerable height, as will be noted from the illustration, and after following the river bottom nearly to the dam it ascends to the plateau, there being an eight per cent. grade that requires a quick turn before reaching the elevation.

On this bank has been constructed an unloading platform, which is illustrated, as well as the plant for making the concrete. The platform and plant are in combination, the purpose being to utilize machinery and economize labor wherever possible. The platform is nine feet above the ground and this is reached by an inclined run about 50 feet long that has a grade of about 18 per cent. The truck can be driven to this platform and then from it without backing. At the centre of the platform is an opening a few inches narrower than the space between the wheels of the truck.

The truck is driven to the platform and the load dumped into the opening when the body is lifted by the screw hoist operated by the engine. Beneath the platform is a pocket with sides inclined to the mouth at the bottom, and under this is a belt conveyor 16 inches width that has a length of loaded travel of 135 feet and moves at a speed of 300 feet a minute. The

Loading Five-Ton Peerless Truck with Steam Shovel at the Gravel Bank.

Unloading Platform at Concrete Making Plant at Dam at Earville, O.

sand or gravel is deposited on the belt and conveyed directly to the concrete mixers. The conveyor is operated by an eight horsepower steam engine and on an incline of about 25 degrees it gives excellent results. The labor of handling is confined to the attention necessary for the engine, and the truck load is quickly carried where it is used in the required proportions. While this work is going on the truck is returning to the gravel bank.

The regular working day is nine hours, and in that time the truck will carry 15 loads as an average, each weighing 11,400 pounds, or a total of approximately 85 tons. In the same period it is generally driven about 33 miles. During night work, which is occasionally necessary, it has been operated with but slightly decreased efficiency. The estimate is that the machine is doing work for which nine two-horse teams and carts and nine drivers would be required, and there is no delay in the supply of material required for the mixing machines. The saving in the cost of the dam by the use of the truck is a considerable item, for W. E. Maxson, superintendent for the Amburson Hydraulic Construction Company of Boston, which is contractor for building the dam, is authority for the statement that the truck is doing at an expense of about \$16 a day the work that would cost about \$56 if horses were used, this being a saving of practically \$40 daily.

The Davis Manufacturing Company, Milwaukee, Wis., and the Rutenber Motor Company, Marion, Ind., have been admitted to membership in the recently organized Automobile Engine Manufacturers' Association. The purpose of the association is stated to be in no manner to restrict competition, but to promote the industry by the exchange of useful information that will stimulate the use of motor vehicle engines.

The demand of the factory of the Goodyear Tire & Rubber Company, Akron, O., for fabric for the manufacture of tires has been such that a night force has been set at work at the mills of the Killingly Manufacturing Company, Williamsville, Conn., owned by the Goodyear company and engaged in the manufacture of a special duck cloth used exclusively for tires.

One of the mining companies in Peru has acquired a five-ton, 50 horsepower Saurer truck, made in Switzerland, fitted with a steel dumping body. Despite the fact that the engine is required to work at an altitude of 13,850 feet, the owner reports that the machine has proven satisfactory in every respect.

With capital of \$10,000 the Direct Drive Axle Company has been organized at Columbus, O., to hold a patent on an axle that will be manufactured in that city. The officers of the company are: President, W. E. Campbell; vice president, I. H. Pleukarp; secretary-treasurer, C. O. Haines.

WANT CAMPBELL IN DUBLIN.

Manager of Boston Show Invited to Direct Civic Exhibition in Ireland.

International recognition of the capacity of General Manager Chester I. Campbell of the Boston pleasure car and service wagon shows is evidenced in the invitation received by him Jan. 27 to direct an international exhibition that will take place in Dublin, Ireland, the coming summer and autumn. The Boston exposition was originated 12 years ago, and each year the display has been larger and better from the viewpoint of the visitors, and while assumedly a local event the statement that it is a New England and Eastern Canada show does not more than reasonably represent the section of the continent from which its patronage is drawn.

The first show was directed by a committee, of which Mr. Campbell, as secretary, was the active director. The following year he was elected manager, and since that time he has been secretary of the Boston Automobile Dealers' Association and of the Boston Commercial Motor Vehicle Association and general manager of the shows organized by them. The success of these expositions led to Mr. Campbell being engaged as manager of the national motor boat shows, electrical, textile and other industrial displays in Boston and in New York and Chicago, and in every instance the results have been gratifying to the organizers.

The success of the shows has been from Mr. Campbell's ability as an organizer and the fact that he knows how to attract and interest the public. He has devoted his time and endeavors to exhibition management for years, and he is without question the best known man in New England, and his reputation for high class attractions has not only insured exhibitors generous patronage, but the people have equal confidence that the shows will have sufficient merit to justify their interest.

The invitation from abroad was cabled by the Countess of Aberdeen, from the Vice Regal Lodge, Dublin, and the exhibition will be of civic character, under the auspices of the Irish Housing & Town Planning League, of which she is president. It is expected that there will be numerous exhibits from housing and city planning associations of America, England and Continental Europe. Mr. Campbell is awaiting complete details by mail before considering the proposal, and meantime he is completing the plans for the annual pleasure car and motor truck exhibitions in Boston next month, and the fourth national textile show in April, which are under his direction.

The machinery is now being installed in the new plant of the Maccarr Company at Scranton, Penn., being removed from Allentown, that state, and in a comparatively short time the factory will be started.

VANBRUNT SELLS FOREIGN TRADE.

New York Man Will Control Distribution of Palmer-Moore Machines Abroad.

The Palmer-Moore Company, Syracuse, N. Y., maker of Palmer-Moore air and water-cooled motor delivery wagons, has made contract with H. D. VanBrunt of New York, under the terms of which Mr. VanBrunt will market its export production aside from that sold in the Canadian provinces. Mr. VanBrunt recently returned from an extended tour to Australia and countries of the Far East, and he has planned to specialize in the exportation of American pleasure cars and motor wagons and trucks. He has projected a selling organization that will consist of 15 men, who will travel in different countries, developing trade and ascertaining the needs of the people in the particular lines they are engaged in. Having direct connection with the American manufacturers he will be in a position to obtain whatever will be best adapted to the requirements of the people of any given locality, and the makers he represents will have the advantage of the constant exploitation of their machines.

Mr. VanBrunt visited Syracuse at the close of the New York automobile show, he being accompanied by William Cowles of Adelaide, State of South Australia, the latter desiring to become agent for a water-cooled delivery wagon that would be adapted to service in the locality where he does business. Mr. Cowles is of the firm of Eyes & Cowles, Ltd., a leading automobile dealer of Adelaide. He selected a chassis which has been shipped around Cape Horn, and will reach Adelaide about April 1. Mr. Cowles is very enthusiastic on the opportunities for motor truck transportation in Australia. The roads, he stated, are generally good. The distances between cities and towns of consequence are so great and the economy of motor truck freightage is so generally realized by mercantile, manufacturing and agricultural interests, that these vehicles will be used whenever possible, for with better transportation decided development is certain to be realized, and the people are concerned in whatever will be promotive. Mr. Cowles was returning, having visited the Automobile Salon at Paris, the Olympia show at London and the national show at New York.

Relative to his own plans Mr. VanBrunt says that when he left Australia in November the business conditions were good in all of the seven Australian states, though the labor party is practically in control of the government and the state and local administrations. Strikes have been numerous, but the people as a whole are very prosperous. Extreme wealth and extreme poverty are conditions rarely met with, and the conditions that stimulate vice and depravity are noticeably lacking in the cities. The intense rivalry in all things between the people of the seven states of the colony, which is at times extremely bitter, has been a decided

handicap in the development of interstate commercial relations. This condition appears to the visitor to be decidedly peculiar. Australia is gaining rapidly in population, Adelaide, the capital of South Australia, having more than 200,000 inhabitants, and Melbourne, capital of the neighboring state of Victoria, has nearly 800,000. Mr. VanBrunt looks for a very lucrative business in Australia and believes that American trade will be materially increased with the completion of the Panama canal.

COLLEGE TEACHING MOTOR LORE.

The citizens of the State of Iowa who desire to obtain motor vehicle knowledge can avail themselves of the course established by the Iowa State College, which has broadened the scope of its engineering department by the addition of instruction in automobile theory and practise. The course is necessarily elemental and abridged, but it is believed that those who desire to obtain practical information can benefit themselves materially by it. According to the plan for the present year the instructor, R. E. Davis, who was connected with the Midland Motor Company as chief engineer, is to give lectures for five days in as many cities as can be reached in the time available, and the students must arrange to take the full course to be entitled to enrollment.

WANTS MOTOR 'BUS FRANCHISE.

The Milwaukee Transportation Company, represented by T. S. Lyons, has made petition to the city council of that city for a franchise for a motor omnibus line from the city hall to the northeastern boundary, covering stated streets. The company proposes to operate 20 machines, making trips at intervals of from two to 30 minutes, charging a 10-cent fare. Mr. Lyons asks for an exclusive franchise and proposes to pay a license fee on a basis of mileage. The petitioner represents the London Omnibus Company, which is operating public service omnibus lines in London, New York, Washington and elsewhere.

SPARK PLUG MEN ORGANIZING.

A committee chosen at a recent meeting of spark plug manufacturers in New York, who gathered as the guests of A. R. Mosler of A. R. Mosler & Co., owner of the Canfield spark plug patent, will formulate plans for an organization in which will be represented practically all who have secured licenses to manufacture spark plugs under the Canfield patent. The body will be protective so far as this may be necessary and generally promotive of the industry.

The capital of the Timken-Detroit Axle Company, Detroit, is to be increased to \$3,000,000, this being demanded by the development of the business.

ADAPTABILITY OF FODEN STEAM TRUCKS.

Results of Six Months' Experimentation by New York Concern in Hauling Construction Materials, Etc.—Ton-Mile Expense of 15 Cents with Coke and Coal as Fuel.

FTER operating two Foden steam trucks for some six months, the Terminal Transport Company, Kingsbridge avenue and 236th street, New York City, feels that it is in a position to offer valuable information as to the adaptability of these vehicles to all kinds of service. The company has utilized these machines in contract haulage work, including handling of building materials, paving materials, sometimes with and sometimes without trailers. A detailed statement of expense indicates that with either the machines may be operated at a cost of 15 cents a ton-mile.

Engine and Boiler.

The Foden steam truck is built by Fodens, Ltd., Loughborough, England. It has an engine of the compound type, the steam jacketed cylinders of which have a bore of four inches, high pressure, and 6.75

long, six wide and three deep. Special reference to the arrangement of body and load will be made later. One of the illustrations shows the driver's seat and indicates some of the details of construction.

Underneath the chassis is a 160-gallon water tank, permitting a supply sufficient for a run of from 15 to 20 miles. The pump discharges through a feed water heater at the left of the engine, into which exhaust steam is led. An injector also is fitted. A steam syphon at the right of the coal bunker, just back of the driver's seat, and 11 feet of hose permit water to be taken from a brook or other source of supply en route.

Other Constructional Details.

A two-speed gear is provided, giving speeds of two and six miles an hour. Drive is by sliding gears on the crankshaft to gears on a fixed countershaft, and thence by roller chain of 2.5-inch pitch to a live rear

One of the Foden Steam Trucks and Two of the Trailers Owned by the Terminal Transport Company, New York City.

low pressure, and stroke of seven inches. The engine is fitted with the Foden high pressure gear, by means of which it is instantly converted into a double pressure, each cylinder receiving steam separately from the boiler and exhausting independently into a smoke stack. This is held to increase power in emergencies, and to make the machine more readily handled in difficult places.

The boiler is built along the lines of the horizontal five boiler and is hydraulically tested to 350 pounds for a safe, working pressure of 200 pounds.

The firebox is made large to take either coke or coal. The total heating surface of the firebox and boiler is 70 square feet.

Water Supply.

Accompanying illustrations set forth the general appearance of the Foden machine, which is rated at 15 tons, and has a load carrying platform nine feet

wide. The radius rods are threaded right and left to permit adjustment of this chain. Two sets of brakes are fitted, in addition to the use of the lever in reverse position. The service brake acts upon the flywheel and is operated by the foot, while the emergency band brake operates on a drum upon the rear axle. Steering is accomplished in the same manner as with the ordinary road roller, the front axle being pivoted at its centre.

The wheels are shod with steel tires, the rear members having broad cleats, closely spaced. Provision also is made for sanding the road to afford additional traction.

Provision for Dumping.

As will be noted, the bodies are arranged so as to be dumped, and this may be accomplished either by hand or by steam. The small illustration shows the crossed belt leading from the flywheel to the pulley on

Driver's Seat and Dumping Mechanism on Foden Steam Truck. the dumping mechanism. The body is hinged at the rear, and the load may be deposited in one place or spread as desired. The picture also indicates the method of raising and lowering the body by hand, a detachable handle being fitted to the shaft protruding between the driver's cab and the body proper.

Kind of Fuel Employed.

It has been stated that the firebox is so constructed that it will take either coke or coal. In England, where a large number of these vehicles have been operated with success for the past 10 years, the fuel most generally employed is soft coal, but there are obvious reasons why hard coal is preferable in this country.

The Terminal Transport Company has experimented with various kinds of fuel, including coke and briquettes, the latter a preparation composed largely of anthracite coal dust and tar. The engineer states that the best results have been obtained with the use of a mixture of Plymouth red ash stove coal and coke, about half and half by volume. He also states that it takes about an hour to get up steam. The bunker holds 300 pounds of coal, and for long runs, extra fuel is carried in bags with the load.

Design of Trailers.

The trailers utilized by this concern were supplied by Scannell & Nephew of London, a firm of motor engineers with which Fodens, Ltd., has a contract for this class of work. They are connected to the truck by a long drawbar with a spring at the forward end, designed to take up shocks. The trailers are fitted with steel tired wood wheels. There is no provision for dumping the trailers, although the rear ends and sides are hinged at the bottom and open outwardly.

It ought to be stated here that Foden steam trucks have been sold for so-called Colonial service in many parts of the world, and statements concerning these vehicles which have been received in this country have indicated that they were particularly well adapted for service where there were no roads, in the generally accepted use of that term. The experience of the Terminal Transport Company, according to its manager, Robert L. Niles, Jr., has been that they are not adapted for service on poor roads.

Distribution of Load.

He says it is necessary to have roads with good foundation, and he explains this statement by calling attention to the weight of the vehicle and the distribution of load. The truck is rated at six to seven tons. Ready for the load the vehicle weighs approximately 7.5 tons. Study of the accompanying illustrations will indicate that a large proportion of the load is carried by the rear axle. Mr. Niles says that the weight to which the rear axle is subjected is about 12 tons. He adds that this concentration of weight can be avoided when the use of narrow cleats and wide spacing is permissible to give traction, but the marking which results on asphalt or bituminous pavements precludes this type of driving wheel in the vicinity of New York. Fodens, Ltd., has produced vehicles of this capacity fitted with rubber tires for use in Great Britain, but Mr. Niles is of the opinion that the cost of such tires is prohibitive when trailers are used.

It has been stated that the truck affords speeds of two and six miles an hour, and while this may appear to be slow, Mr. Niles suggests that it must be remembered that ton-mileage is the criterion of effectiveness in any vehicle. The experience of the company has indicated that it is entirely practical to run slowly and draw a big load, and that the Foden is capable of 54 ton-miles an hour. A standard load with this concern is six tons on the truck and three on a trailer, although with smooth roads and easy grades a total of 12 tons on the truck and trailer has been handled advantageously. Mr. Niles says that by hauling a trailer, which he believes must be done to secure maximum efficiency from machines designed for heavy pulling, it is possible to reduce the cost a ton-mile to 50 per cent. of that of horse haulage.

Use of the Trailers.

With slow loading materials, it has been found that three trailers can be worked with success in the following manner: One trailer at either end of the route and the third on the way. By this is meant that one trailer is left at the dock, for instance, to be loaded, while the truck is hauling a fully loaded trailer to the end of the route, where it dumps its own load, picks up an empty and returns to the dock, while the loaded trailer is being emptied.

However, it is maintained by Mr. Niles that it is not always possible to utilize these trailers with success, owing to the fact that they are not reversible. With reversible, end dumping trailers, such as can now be obtained in the American market, he feels that the cost of haulage with all classes of material can be reduced under all conditions but one—a short haul with material that can be dumped. In this case, he suggests that it might take more time to manoeuvre the trailer than would be saved by its use.

Cost of Operation.

Concerning the cost of operating these vehicles, Mr. Niles says the machine will consume from eight to 16 gallons of water to the mile and from 10 to 20 pounds of fuel, depending upon the condition of the

and surface and upon the grades. An asphalt or luminous surface may double the tractive effort necessary to move the load. He adds that experiments made by the company have indicated that soft coal is best for making steam, but introduces smoke and fumes. Coke is clean, but has insufficient lasting qualities and is rather too bulky. The cheaper grades of coal and the briquettes are held by him to be absolutely worthless.

The Detailed Figures.

The ton-mile cost stated above is based on a daily mileage of 30. The figures presented below are taken from the report supplied by Mr. Niles to the treasurer of the Terminal Transport Company in his annual report at the close of 1913. They represent a monthly average, based upon the actual cost of the several items, although it is probable that there may be some variation in the matter of mileage from month to month. The report covers the cost of each item and its percentage of the total for the two Foden steam trucks and the three trailers owned by the company, and is as follows:

Average Monthly Cost of Operating Two Foden Steam Trucks and Three Trailers.

Depreciation at 10 per cent a year.....	\$84	8.3
Insurance, etc.....	25	2.4
Repairs, 10 per cent a year.....	84	8.3
Garage rental.....	25	2.4
Coal, six tons at \$8.....	48	4.7
Coke 150 bushels at 11c.....	16	1.5
Oil, 25 gallons at 40c.....	10	1.0
Waste, gloves polish, etc.....	4	.5
Permits, licenses, etc.....	4	.5
Engineers, two, 26 days at \$5.50.....	286	28.0
Helpers, two, 26 days at \$3.....	156	15.2
Manager's salary.....	200	19.6
Watchman, at \$3 a day.....	78	7.6
Totals.....	\$1020	\$100.0
Average cost a machine a day.....		\$19.60
Average cost a machine a ton-mile.....		0.15

It will be noted that depreciation is based upon a life of 10 years for the vehicles, and an allowance of another 10 per cent. is made for repairs. Mr. Niles states that it is the intention of the company to provide this reserve, whether or not it is utilized, in order to insure a life of 10 years as figured. The total repair expense for the past six months has been \$40.

By far the largest item of expense is the engineers' wages. The Terminal Transport Company believes that it is economy in the long run to place its expensive machines in charge of thoroughly reliable and competent men, and that such men deserve at least \$30 a week. Since the items of depreciation and repairs are almost entirely in the hands of the engineers, the company feels that a lower wage would mean less care in the driving of the trucks, leading to expensive breakdowns and vexatious delays.

In enterprises where haulage

is but an incidental part of the business, neither a watchman nor a manager would be chargeable to the machines alone, and the cost of haulage would be reduced to 11 cents a ton-mile, according to Mr. Niles' analysis of the figures.

"SAFETY FIRST" AT ALBANY.

The Albany Automobile Club has launched a "safety first" campaign in Albany, N. Y., and the members have undertaken to educate the people of the city to the need of protecting themselves in the streets from traffic dangers. The club has caused large posters to be placed conspicuously about the city, it has distributed literature to the people generally and to numerous organizations in particular; it has been given co-operation by the school department and the school children have been advised by the distribution of printed suggestions, and some of the public service corporations have joined in the work. The club has undertaken to influence drivers of all vehicles to observe the laws and ordinances governing street traffic, and has sought to have the regulations enforced should there be any disposition to disregard them. The managements of the moving picture theatres of the city have also joined in the movement, and films that will demonstrate the need of attention to safety before all else have been made in Albany. These are to be shown in that city, and when they have served their purpose they will be sent elsewhere for exhibition in connection with similar campaigns.

Armored Bank Van in Paris—One of the leading banks in Paris has supplanted its unprotected horse wagon with an armored motor vehicle. The whole body is covered with steel plates capable of resisting rifle shots, and the maximum protection is afforded the driver, consistent with clear vision for driving under the traffic conditions which exist in a large city.

Driver Dumping a Load of Material from Foden Steam Truck by Utilizing Power of Engine.

SUBSCRIPTIONS:

The United States and Mexico, the year \$2 in advance; Canada and Foreign Countries in Postal Union, the year, \$3 in advance. Twenty cents the copy.

ADVERTISING RATES.

Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.

Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.

Entered as second class matter, February 25, 1911, at the Post-office at Pawtucket, R. I., under the Act of March 3rd, 1879.

MOTOR TRAFFIC REGULATION.

Anticipated or pending legislation in many of the states ought to receive the careful attention of all owners of motor vehicles. No one will deny the need of such regulation as will afford protection to life and property and conserve the best interests of all. Were the legislators to seek the co-operation of the owners and users of machines, create their interest and consider their views, instead of regarding them as indifferent to the public welfare, a great deal of friction and antagonism might be eliminated to the benefit of all.

Taxing a vehicle will not afford a larger measure of safety nor will it insure the competency of the driver. State licenses to drive are usually granted after a perfunctory examination. Where so great responsibility lies much greater care should be taken in ascertaining the qualifications of an applicant, and driving license should be suspended pending inquiry following every accident, not to be restored unless investigation shows that driving fault did not exist. The prospect of loss of employment in a state, or in as many states as would adopt such a law, would insure care in driving that does not now obtain, and no employer could consistently object to such a regulation, as the effect would be his protection.

THE BOSTON TRUCK SHOW.

The only exclusive exhibition of power wagons of the year will take place at Boston next month. This

will be the third show organized by the Boston Commercial Motor Vehicle Association, and with the experience from previous displays every endeavor will be made to attract those who are desirous of purchasing machines or are investigating transportation problems with a view of installing motor equipment if its efficiency can be established.

No one will take issue with the statement that the New England market offers very large possibilities. The need of economic highway haulage was never more keenly realized, and turning from propositions in which there may be doubt, there are thousands in which motor vehicles can be advantageously utilized. The show will afford opportunity for gaining information and making comparisons that would not be practical, if, indeed, they were possible, and this buyers are quick to realize.

The advantages of representation in an exhibition of this character, where the qualities of machines can be demonstrated, cannot be measured by money valuation, but results will obtain proportionate to the merits of the exhibits and the ability of the salesmen. Wide publicity will be given to the show and there is no question that it will draw people from all New England. It will take place just before the opening of the season for out-door construction, when the demand for vehicles is at its height. The exhibitors will concentrate their endeavors on the exhibition, and the knowledge resulting from selling experience ought to be very beneficial.

PREVENTING TIME LOSSES.

Those who contract for or pay for special haulage are often absolutely indifferent to the delays that are resultant from failure to have freight ready when called for, or from conditions that retard unloading. Apparently the belief exists that vehicles can be kept waiting to convenience them, and that remonstrance is not justified because patronage may be bestowed wherever desired. From this point of view competition impels tolerance of conditions that are often hardships. The time of a vehicle and its crew has a distinct money value, and were waiting time paid for decided changes would undoubtedly follow the presentation of bills. Were penalization similarly exacted from the owners of vehicles for delays for which they were responsible there is little doubt that they would be as prompt as they desire their customers to be. Such arrangement as has been proposed could not be objected to, and could profitably be entered into by business men.

The proposition would not mean a loss to either interest, but would impel attention to detail that is now generally neglected. Shippers must regard time with reference to the leaving of trains and vessels, and there appears to be no good reason why local transportation, in which the delays are constant because of no systematic provision to prevent them, should not be considered by business men and haulage contractors.

ELECTRIC VEHICLE PRACTISE.

Vehicle Mileage Determined from the Rating of Battery Cells---Discharge Capacities and the Starting and Finishing Rates for Charging Some Standard Types---Use of Indicating Instruments and Specific Gravity Readings.

By William W. Scott.

THE work that is required of a battery should be very carefully considered by the purchaser of a vehicle. By this is meant that the battery should be of such size that it will supply all the energy required to perform a certain work, which may be taken as an average mileage. To illustrate: A battery may be composed of 44 cells with capacity of 380 ampere-hours, and assuming the normal discharge rate to be eight hours this would permit the use of 47.5 amperes for that period of time. If six amperes of current are necessary to move the vehicle an average mile this means that 7.916 miles an hour can be driven without exceeding the prescribed rate of current consumption, and theoretically the mileage would be 63 before the battery was reduced to exhaustion. But while an average mile is referred to, one must understand that a higher rate of current consumption is necessary when the vehicle is loaded. When battery capacity is stated it can be accepted as conservative, and when expressed in miles in manufacturers' ratings means that a full load can be carried half the distance, a half load carried the entire distance, or a 75 per cent. load carried 75 per cent. of the distance. Rating of lead-acid batteries is based on new or comparatively fresh cells, for there is a shrinkage in capacity as the cells age, and this will continue until but little energy, perhaps no more than will yield several miles operation, can be supplied from them. Such a condition is unusual, for renewal or reconstruction is generally decided on before a battery has so greatly deteriorated, because of the necessity of operating the vehicles a sufficient distance and period to insure a profit from them.

A battery should always be chosen that will do whatever work is required, and in some instances extra sizes are installed because of the conditions of work. A large battery weighs more and additional power is required to drive the machine, and while greater mileage can be obtained no larger load can be carried, or, if a bigger freight is desired, the mileage cannot be increased. This statement is made in a general way, for results may be attained that will not precisely parallel the illustrations given. One must understand that before consideration of the battery one must ascertain what facilities are available for charging, because the capacity of the feed or main line in voltage must be sufficient to afford a complete charge.

Assuming that the battery has been selected with reference to the greatest efficiency that can be determined by known capacity and estimate of work, and

that the machine is to be operated daily, provision should be made for records that will insure complete knowledge of work and operation, for these will be found of decided value. Preferably the records ought to be on forms that can be filled conveniently and which may be preserved in files or books. Electrical engineering and electro-chemistry are exact sciences, and accuracy is imperative if rule or formula is to be followed. This does not mean that exactness is absolutely necessary for reasonable success in battery operation, but the greatest efficiency can be obtained by adherence to standards, and "guessing" is very certain to lead to neglect and inferior service.

The lead-acid battery cell is rated at its greatest efficiency when the eight-hour rate of charge or discharge is maintained. The loss in capacity with the decrease of this rate has been explained. There are occasions when the amperage drawn may be very much in excess of the normal rate, but such drains are not continued for any extended periods. The makers, however, give ratings that are based on four, five, six, or eight hours, and if these are not exceeded the efficiency will be realized. This statement is made to emphasize that the nearer the battery is operated to what may be regarded as its standard of work the greater economy will obtain.

Every battery is plainly marked so that there could be no mistake made by any person using ordinary care in any work upon it, and an operator with experience in battery manipulation could, by following extremely simple rules, establish any condition and with absolute certainty reach any result desired. As a matter of fact there is no reason why an error should be made, and it is practical to expect that a required condition can be attained whenever desired.

For regular charging a standard of 2.5 volts a cell can be considered the maximum requirement, and 1.8 volts the minimum that is permitted. The product of the number of cells multiplied by 2.5 will give the line voltage necessary to obtain a full charge. Vehicle lead-acid batteries range from 16 to 48 in number of cells, and are made up in multiples of two, so that, to illustrate, the 16-cell battery would require 40 volts, and the 48-cell battery 120 volts, or three times as much. But if the line voltage is 120 there will probably be a slight loss from the resistance of the line and the cells, and the probable maximum will be 115 to 117, depending upon conditions.

The first requirement in charging is to know the capacity of the battery and the facilities available for

this work. The equipment ought to be of the best, for it is then dependable. The following tabulation is standard with the manufacturers of the different batteries specified:

Considering the foregoing tables it will be noted that the cells differ in ampere-hour capacity, and that the discharge rates range from four to six hours. Obviously the cells with the longest discharge period will have the greatest capacity, that is, that a cell rated at 25 amperes for six hours, or 150 amperes in all, will yield less of that capacity as the discharge is hastened, and will somewhat exceed it if the discharge is made slower than the rate stated. For this reason the rating of cells can be regarded as a standard conservatively placed by the manufacturer, which will undoubtedly be exceeded when the cells are new. But the temperature, the age of the cell, and the condition of maintenance are all factors entering into efficiency. One must remember that the lead-acid battery cell is gradually deteriorating, and the ratio of deterioration is proportionate to the care.

The cells of a secondary lead-acid battery can be charged only from a direct current, which may be primarily generated as direct, or generated as alternating and converted to direct by rectification, regeneration or conversion, but the manner of determining the condition of the charge—the energy accumulated—may be by indication of a voltmeter or by the specific gravity of the electrolyte. Of these the former method is generally used, but the latter occasionally is utilized. Specific gravity readings, however, are necessarily used to indicate the condition of the solution in the cells, and where the voltmeter is used one may say that the method is a combination of both.

In previous chapters the value of specific gravity indications has been emphasized, and further explanation is not necessary to make the facts stated clear to the reader.

The charging may be from any line that has a sufficiently high voltage and amperage, and this may be carried direct to the battery without even the use of a switch, but the switch is always utilized unless in the event of extemporized apparatus because of the greater safety and convenience. The line is connected with a charging panel or switchboard, and on this are usually the switch, the voltmeter and ammeter, and the current passes through a resistance coil or rheostat that the amperage may be varied. Occasionally wattmeters are installed on the panels for the purpose of indicating the amount of current that is used in charging. Without the wattmeter the quantity of current used can only be approximated.

The principle of charging is this: The battery has a maximum capacity rating which is the number of cells multiplied by 2.55, which will give the necessary voltage when the cell is fully charged, and assuming that a battery is reduced to the minimum permissible, which is indicated by the number of cells multiplied by 1.8, the voltage must be increased from the minimum to the maximum. This is done by connecting the charging lead with the battery and permitting the current to flow into the battery at the voltage and amperage stated. As will be noted the amperage for cells is variable, which can be ascertained by reference to

tables previously given, but the voltage is practically standard for batteries of the same number of cells, and the following table will give what may be regarded as a satisfactory approximation, although the temperature at the time of charging and the age of the battery will be factors of some importance. A new battery will show higher voltage readings than an old battery, and the variations from this influence cannot be stated with exactness:

Voltage Rates for Charging.

No. cells	Voltage at start of charge	Voltage at which amperage should be reduced
12	26	31
14	30	36
16	34	41
18	39	46
20	43	51
22	47	56
24	52	61
26	56	66
28	60	71
30	64	76
32	69	81
34	73	87
36	77	92
38	82	97
40	86	102
42	90	107
44	95	112
46	100	117
48	105	123
50	110	128

Considering these figures for a moment one should understand that they are applied to cells that require what is referred to as a full charge, and when a full charge is not needed and the reading of the voltmeter or the hydrometer shows a higher indication than stated at the beginning of the charge, that the amperage of the current should be reduced when the voltage specified is reached. That is, the battery should be given such charge as is necessary to bring it up to the maximum.

The voltage of the cells in theory should increase uniformly and all should indicate the same. A battery will be influenced by a single cell, and any condition that will result in a lessened voltage will be noticeable. In the event of a defective cell restoration is necessary. In other words, the battery cells must be in practically the same state of efficiency to obtain the fullest measure of productiveness.

When charging is done by gravity the equipment necessary is much simpler. The only indicating instrument necessary is an ammeter, and generally the charging is governed by the specific gravity readings of a pilot cell, which is selected from a centre group. The current is permitted to flow into the battery by closing a switch, and when the specific gravity of the pilot cell or cells indicates the standard at which the amperage should be reduced the reduction is made and the charging is continued, being regulated by the condition of the electrolyte. It will be evident that the charging cannot be done by following a tabulation unless the conditions were precisely the same, and obviously every battery will differ. The cells will not have precisely the same indication, and the other factors, age, temperature and other conditions, will have influence. When gravity charging is practised, how-

ever, the cells are closely observed and these will indicate with absolute certainty the condition. It is practical, however, to establish a definite standard for any battery and when this is shown in the specific gravity reading to reduce the amperage to the required rate.

All battery manufacturers recommend that charging be done where a reasonably even temperature can be assured. Engineering standards are usually based on 60 degrees Fahrenheit for the electrolyte, and this is corrected for higher or lower temperatures. Similarly engineering data are based on use of 1.842 acid for the solution, while the commercial product, almost always used for practical purposes, has a standard of 1.835. Taking a standard the battery engineer makes recommendation of a maximum specific gravity that represents the cell fully charged, and with this as a basis a tabulation is worked out that represents the required maximum at different temperatures. For instance, one manufacturer gives 1.300 as the specific gravity of his battery when shipped from the factory, and states that in practical operation it may be regarded fully charged when the specific gravity is 1.285 at 85 degrees Fahrenheit. Assuming a solution of 1.300 density at 60 degrees: The variation of temperature will vary the density from about 1.285 at 100 degrees to 1.309 at 30 degrees, or a difference of about one-third of a point in density to each degree of temperature. This variation will be in direct ratio with the density and the temperature.

It is evident that a marked error could be made disregarding the change in temperature, and while correction is practical by the application of the rough rule stated, knowing the temperature, the density, and having a standard by which the rule can be applied, complications can be avoided by keeping the room where the battery is charged at or as near as is possible to a known degree of heat. To illustrate: The approximate readings of an electrolyte that would be standard at 1.285 at 85 degrees would be 1.284 for 88 degrees, 1.283 for 91 degrees, 1.282 for 94 degrees, the density lessening up to 110 degrees, which is the critical point, and it would similarly increase as the temperature is decreased, showing 1.302 or thereabouts at 30 degrees.

Batteries, unless there is special reason, are shipped assembled and fully charged. When shipped with a vehicle the battery is charged and, unless it has been in transit for more than three days, needs no attention, but if it has been on the road for four or five days or a week, it is well to give it what is known as a freshening charge, which is given slowly and at low amperage, generally at the finishing rate, this being intended to reduce any sulphate that may have formed and to bring it to a state of highest efficiency. This charge may be stopped when the cells "gas" freely, for overcharging is to be avoided in such cases as this.

Charging had best be done by system or formula. That is, the work ought to be done in precisely the same way each day, or when the battery is charged, as

this will insure every detail being given the attention necessary or desirable. Record forms ought to be procured and provision made for filing these, so that reference to these will at all times afford useful information. These should be simple, but they ought to include the date, the number of the battery or the vehicle, the station and circuit if there is more than one machine, the time charging was begun, the starting rate of amperage, the voltage indicated at the start, readings of the voltage every half hour, the time amperage was reduced, the time charging ceased, with the final readings of both voltage and amperage, the condition of the battery as noted by the observer, and, if a wattmeter is used, the total wattage used in charging.

The battery cells are arranged in crates, each crate being a unit and removable from the battery box, and the cells are coupled by the connectors that are fitted from each positive to each negative terminal, leaving one negative and one positive terminal of each crate available for connection with other crates, and when the battery is ready for use each cell is connected, positive to negative, with the positive terminal of one end cell and the negative terminal of the other end cell connected with the power wiring. This arrangement is known as "in series", and this affords the use of the combined voltage of the cells and the amperage of any one cell. Thus a battery may be rated at 115 volts and 380 ampere-hours. Examination of the cells will show that all the terminals are designated, although the method of marking may differ. For instance, some makers use the plus + mark for the positive poles and the minus — mark for the negative. Others use red and black fibre washers for the same purpose, the red being positive, and sometimes the marks are filled with paint or enamel to insure certain identity.

When a battery is installed in a vehicle it is connected with the power wiring, which is installed so that the different combinations desired may be obtained by the movement of the controller handle, this grouping the cells so as to obtain the most efficient service with what proportion of power is desired. The battery is also connected with the charging wiring, which is coupled to the terminals of the end cells. This wiring is connected with the charging receptacle, which is installed conveniently in the vehicle, being usually inset in the frame where it is protected.

When the crates of cells are placed in the battery box and the end cells of the crates and the end cells of the battery connected the arrangement of the power wiring need not be considered. With the cells connected in series the battery is ready for charging or for use.

During charging battery cells liberate some oxygen and considerable hydrogen gas, either of which is very inflammable, and for this reason no naked flame should be permitted near the vehicle, but as good ventilation as is practicable should be insured, as this will allow the gases to escape. The battery box should be opened and the rubber vent plugs of the cells removed. Be-

charging the controller should be placed in the position, or in the charging location if such is desired, and the switches opened. The lamps should be allowed to burn and the horn or bell should not be sounded, for there is a probability of the heavier age destroying them.

The cells ought to be kept filled with electrolyte to the height recommended by the battery manufacturer, usually instructions are provided with each vehicle that specify the depth the element should be submerged. Generally the top edges of the plates should be half inch below the surface of the solution, and if solution is low, for it is constantly dissipated in charging, the level may be restored by the addition of distilled water. There can be no loss of acid unless by leakage of a jar or by slopping, and if there is need of additional electrolyte this can be provided as will be noted later on. The addition of water to the cells is known as "flushing" or "equalizing". After the battery box has been opened for ventilation the tops of the cells should be wiped of dust or any other accumulations, then the vent plugs can be removed and the condition of the individual cells determined. The water should be added to the cells before charging is begun.

Distilled water can be procured in whatever quantity desired and should preferably be kept in five-gallon carboys, which can be handled conveniently. The water can be distributed from the containers to the cells in a glass or earthen vessel that has a "nose" which will facilitate pouring, or a glass funnel may be used with the glass or earthenware pitcher. Metal vessels of any kind or of enamelled iron or steel should not be used. The vessel used should be kept clean and free from dust.

"Equalizing" is necessary only when the level of solution in the jars is low, and an interval of several days, or perhaps a week, will probably be found sufficient to be often enough to add water to the cells. One can judge much better after knowledge of the work done with the battery and observation of the conditions resulting from work and charging. But before preparing for a charge, the state of the solution should be noted when the vent plugs are removed and there be need water can be added.

(To Be Continued.)

The American Taximeter Company, New York, has purchased the Delivery Supervision Company, maker of the Recordograf, an instrument recording time, speed and distance driven, acquiring its stock, good will and patents, and it is expected will continue the manufacture of the machines, cast supply parts and maintain those now in use.

Peerless Motor Car Company, Cleveland, O., has paid its last dividend on preferred stock at the rate of 6 per cent., this being the same as has been paid by this concern.

LARGE TRUCK TIRE MILEAGE.

Union Transfer Company Gets from 12,900 to 25,300 Miles from Shoes.

The results obtained by the Union Transfer Company of Philadelphia, Baltimore and Washington, which has contract for handling the baggage and other transfer work of the Pennsylvania Railroad Company in the three cities named, has been so greatly in excess of the average service from motor vehicle tires that it is worthy of especial notice. The company operates trucks between the different passenger terminals of the three cities and these are used in all kinds of traffic and in conditions that would be regarded as at least the equal of those obtaining elsewhere. The machines are used rationally, however, and this fact alone is believed to be the reason why the tires have given such exceptional results.

A conspicuous instance is that of a truck equipped with Goodrich wireless truck tires which was placed in service in June, 1911. This machine was used constantly and the first replacement was in January, 1913, when a rear tire that had been driven 12,900 miles was replaced. The mileage of the truck was considerably increased in the next few months, for in April, 1913, when the second rear tire was renewed the old shoe had been driven 17,000 miles. The following month a front tire was taken off after it had been used for 18,800 miles, and in September, 1913, the other front tire was replaced, this having a mileage of 25,300 miles. This gave an average of 14,950 miles for the rear tires and 21,650 for the front tires. Since the renewal of the rear tires the truck has been driven 12,000 miles and the shoes have not yet reached the limit of usefulness. It is possible that they may be driven for several thousand miles.

In the opinion of the Philadelphia representative of the maker of the tires the large mileage is resultant from the driving of the machine. It has been used in good street conditions, has never been overloaded or driven at excessive speed, and the driver does not drive in car tracks. He believes that any other truck in normal service, and used in the same manner, ought to be equally satisfactory as to tire wear.

The Electric Steel Company, Indianapolis, Ind., which is shortly to erect a factory at Speedway, a suburb of that city, has engaged James M. Ryan, formerly in charge of the steel casting department of the Canadian Pacific Foundries Company, Ltd., Montreal, P. Q., as its factory manager.

The capital stock of the Bessemer Motor Truck Company, Grove City, Penn., has been increased to \$300,000 from \$100,000, and this will be used to generally develop the rapidly increasing business of the concern. Factory expansion is expected to follow in the early spring.

CAN DEVELOP ALASKA WITH TRUCKS.

Road Board Recommends Improvement of Trail Prospected Last Summer with White Wagon Because of the Material Benefit That Will Follow Road Building.

THE demand that now exists, or may be developed, in the District of Alaska for motor vehicle transportation, is a subject that has been given some attention by those engaged in the service wagon industry, and it is of greater interest at the present time for several reasons. Chief of these is the fact that the people of the district are extremely interested in development, and in this work the national government has actively co-operated. As the market there is protected by tariff and by the cost of water and rail transportation, as well as against foreign competition, there are those who may believe that Alaska can be profitably exploited because of the lack of railroads and that the rivers that are navigable can only be used for a part of the year, usually from May to October.

No motor vehicle was ever driven in Alaska until late in the summer of 1911, when Dr. Charles G. Percival took a pleasure car from Skagway to Carmack's and return, driving a part of the distance over the

track of the Yukon & White Horse railroad. This was an experiment that created a great deal of interest among Alaskans, for from October to the latter part of April the ground is frozen and as the snow does not accumulate to great depth the surface is solid and can be driven over, and there was belief that during that period of the year motor vehicles might be practical for transportation on some of the larger and more important trails.

In 1912 several motor cars were taken into Alaska, practically all of them being carried up the Yukon river on steamers and delivered to owners living in villages along the banks of that stream. Just what success was secured from them is not definitely known. Several tractors were also sent to the interior from Yukon river villages, and these are probably in service.

Last year the board of road commissioners of the district made experiment with a White delivery wagon

On Alaskan Trails with a White Truck: A, Road Work Along the Military Telegraph Trail Through a Typical Delta Country; B, Cliff Trail Through an Ice Canyon on the Coast Range; C, Arrival at the Mining Town of Fairbanks; D, Camping on the Gunecreek Flats in the Valley of the Delta River; E, Street Scene in the City of Valdez; F, Volcanic Wilderness in the Alaska Range, Through Which a Road Will Be Built.

500 pounds capacity, which was driven from Valdez to Fairbanks and return, and a summary of the report furnished by the maker of the vehicle, was given considerable publicity. The supposition may have been that this journey, and the use subsequently made of the wagon during the remainder of the season established the utility of motor conveyances in the district. The intense cold of the winter may not prevent the use of motors, and the real difficulty would seem to be starting when the temperatures are low, but the use of pleasure cars would appear impracticable, according to the report made by Lieut.-Col. Wilds P. Richardson, president of the board of road commissioners for Alaska to the adjutant-general of the United States army relative to the progress of road construction in the district for 1913. Col. Richardson speaks with facts as he has observed them, and he does not encourage motor car touring. He does, to some extent, favor the utilization of motor wagons or trucks. In the main, however, he maintains that in most of Alaska the use of wheels is now impracticable, if not impossible, and there is no reason to expect a change for a considerable length of time.

Physical Obstacles to Development.

The report that directly bears on the possibilities of vehicle use states that: "There is little of level ground in the territory except the moss covered tundra far north and northwest. The coastal region as far as Cook Inlet is extremely rugged and is wet and heavily timbered, especially on the hill slopes, the timber becoming lighter toward the interior. The valleys of the interior or central Alaska are fairly well timbered near the streams, and are also with a dense growth of underbrush, over a blanket of moss, beneath which the ground is usually frozen to great depth. These valleys are crossed in summer through the melting snow and are thawing into morass and swamp, through which travel on foot or on horseback is a slow and arduous process. As one leaves the stream valleys the ground becomes lighter, and on the hill slopes fairly good road may be found, and in a few places considerable areas of dry gravel beach exist, but nowhere is it possible to use wheels for any considerable distance, except on some sort of prepared roadway. It is due to these physical conditions more than anything else that Alaska has remained so long an undeveloped and an unknown country."

Richardson, after a reference to the work of previous expeditions to Alaska, under command of Joseph H. Herron of the Second Cavalry, and many officers, who were the first to discover the routes from the coast to the more important points, tells of the various congressional appropriations for military and post roads and of the manner in which that money was expended.

"The wagon roads constructed may be described", he says, "as good country highways intended to meet the year-round traffic of considerable tonnage. They are graded with suitable grades, crowned, ditched and

drained, and corduroyed or planked where necessary. The winter sled road is an inexpensive form of construction adapted to the requirements of winter travel in portions of the interior. The winter travel begins in early October and lasts to about the end of April. The trail differs from the winter sled road only in being narrower and with less attention given to grade and surface inequalities."

Large Cost of Road Construction.

The average cost of road construction in Alaska, Col. Richardson adds, is about 2.5 times as great as the cost of similar work in the United States, but this difference, he prophesies, will gradually be reduced, largely by the results of the work itself, and by other improvements in transportation conditions, and as the country becomes better supplied.

"The benefits derived from this work", he continues, "are most marked, although the roads constructed so far constitute only the beginnings of a proper road system for the territory. Data in the office of the road commission show the cost of transporting freight and supplies during the year over the roads built by the commission at the prevailing rates to have been \$1,243,735. It is estimated that this amount of freight would have cost, based upon the rates prevailing in the various localities before these roads were constructed, \$3,385,412 had these roads not existed. The saving thus shown as directly due to the construction of these roads amounts to \$2,141,677, a sum not far from the total amount expended on the road and trail system in the territory, or about 16 per cent. of the mineral production of Alaska for 1912. It is doubtful, however, if anything like the amount of freight here involved would have been transported without the roads, and the indirect loss to output and development cannot be easily estimated.

"The business of mining involves the transportation of a large amount of tonnage. As noted in last year's report, there passed over one short road in the Nome district during the summer of 1912 15,000 tons, representing a saving to the shipper of \$5 per ton over the rate prevailing before the road was constructed. This road paid for itself nearly eight times in six years.

Practical Test of Motor Trucks.

"Although the board makes no pretense of having built roads adapted for automobile traffic, machines are used under the ordinary summer conditions about Juneau, Fairbanks and Nome. Several trips were made with machines during the past summer from Fairbanks to Chitina and to the coast at Valdez. The road commission placed a field truck of three-quarter ton capacity, of the type being experimented with by the quartermaster and medical corps of the army, on this road during the latter part of the summer and fall for the purpose of trying out the machine for supply and maintenance work, and to test the availability of the road for such travel. The truck left Valdez July 28 and arrived at Fairbanks Aug. 6; left Fairbanks Aug. 9 and arrived at Chitina Aug. 15; left Chitina Aug. 16, returned as far as Gulkana, thence back to

Valdez, arriving Aug. 19. The distance covered was 922 miles, making about 50 miles per day. The car while running averaged between eight and nine miles an hour. In some stretches as high as 18 miles per hour was made, while in others progress was slow. In some instances the car had to be helped through soft spots on rather heavy grades, but this was not actually necessary for a total distance of a mile throughout the whole length of the road. The president of the board came with the machine from Fairbanks to Chitina, and the engineer officer from there back to Gulkana and out to Valdez. The truck has done some good work on the road near Valdez since.

"This road from the navigable waters of the Tanana to the coast is 419 miles in length, including the Willow Creek-Chitina branch. It crosses two mountain ranges, also numerous rivers and glacier streams, several of which remain to be bridged. It is estimated that an expenditure of an average of \$1500 per mile would improve it to the condition of a very fair automobile road, capable of sustaining any traffic likely to pass over it. Maintenance cost will always be rather high, principally on account of the cutting banks and shifting channels of all streams fed by glaciers. The improvement of this route to the condition mentioned above, with a systematic plan of maintenance and with a regular mail service established over it in summer as well as winter will, it is believed, be of very great benefit toward the development of the territory. Mail could be delivered in Fairbanks in seven to eight days from Seattle, as against an average of 20 or more days by the river route, as at present.

National Appropriations Necessary.

"For this work and for improvements and extensions of the road system in other parts of the territory, all greatly needed, some specific enactment of Congress seems necessary. This maintenance, of necessity, means a slight improvement in the condition of the road from year to year."

In the opinion of the board of road commissioners the physical conditions in Alaska call for an excess proportion of wagon roads, compared to railroads, over that found necessary for systematic transportation development in any part of the United States.

"Our board", Col. Richardson concludes, "specifically disavows any intent to set forth views in opposition or discouragement to railroad construction in the territory under proper limitations, but, after several years of careful observation and study of the land transportation conditions and of the natural inducements to development and to settlement which exist, is convinced that no rapid or general development will follow the construction of trunk lines of railroad to the interior unless preceded or accompanied by the construction of numerous wagon roads and trails as feeders, and even then the development will be slow. As the territory develops the demand will be for a multitude of short roads between the deep sea channels of the coast and the streams of the interior, with certain trunk roads leading from the interior to the coast."

ANTAGONISTIC LEGISLATION.

In practically every state where the legislature is in session there is reason to believe that measures more or less antagonistic will be presented, and these are certain to have the approval of a sufficient number, at least, to insure enactment in the absence of concerted action by the owners and users of motor trucks and wagons. Where a bill is regarded as a party measure it has the strength of organization to agitate for its passage, and when advocated as public need there is apparently no reason why it should be opposed, unless those who will be affected can present sound argument to show that it will be inimical to business interests.

One of the conditions that will militate against the success of those who own or use machines is the general lack of organization. In some states the business interests are represented to a considerable extent by clubs and associations, but in others the only possibility is to arouse a sufficient number to oppose whatever legislation may be proposed. Experience has taught the necessity of having the leadership of men who are aggressive and yet diplomatic, and men of this caliber usually have business interests they cannot well afford to neglect.

Permanent organizations of motor truck owners are not only desirable, but are necessary. Legislation is but one consideration. There are numerous conditions that could be investigated and remedies recommended, and these require constant attention if practical results are to be obtained. The pendency of bills in legislative bodies may be a need for immediate activity, but there is every logical reason why associations should be formed and their endeavors concentrated for the benefit of the members.

The branch of the H. W. Johns-Manville Company at Toronto, Ont., is now located at 19 Front street, East, where it has a store and warehouse with about 35,000 square feet of floor area. This expansion is necessary to meet the demands of increased business.

The capital of the Long Manufacturing Company, Detroit, Mich., maker of radiators and other motor vehicle equipment, has been increased from \$300,000 to \$400,000. The business of the concern will be correspondingly increased.

E. A. Williams, Jr., has been made assistant general manager of the Gramm Motor Truck Company, Lima, O., succeeding Harvey L. Hooke, who has been placed in charge of the plant of the Garford Company at Elyria, O.

The Mora Power Wagon Company, Cleveland, O., has been placed in the hands of Frank H. Adams as receiver. Whether or not the company will continue has not as yet been decided.

COMMERCE 1000-POUND DELIVERY WAGON.

ECIALIZING a single vehicle, the Commerce Motor Car Company, Detroit, Mich., produces a very wagon of 1000 pounds capacity that is mainly by the maker to have qualities that adapt it for great variety of service, while its design and construction are such that it can be operated with a very measure of economy. The machine is offered on the market at a very moderate price and it has a simplicity of operation that recommends it to those who desire to secure dependable equipment at what can be regarded as minimum expense.

The company was established three years ago for the purpose of developing and building vehicles that would be in general demand and supply the need of those who used single-horse wagons, but who sought to utilize motor wagons to serve longer routes and larger numbers of customers, and to minimize time in delivery and increase the area of the section in which business was transacted.

One of the engineering propositions considered was the character of power plant that would have sufficient, but not excess, power, and the application of energy so that it could be ample in practical service under all conditions that could be normally met with. Simplification of construction, that labor in care and maintenance be minimized, was another important consideration and quite as necessary was a margin of safety which would insure endurance.

Practically Developed Machine.

In the choice of motor a type with a long stroke was decided on because of the greater efficiency at low speeds, which would also permit of fuel economy at all times, and a friction form of power transmission was adopted, as this would allow the use of the engine at practically its greatest productiveness under all of the extreme variations of speed. By this it was that this combination afforded a sufficient power for a vehicle of this capacity and insured economy of operation, besides having the additional merit of being extremely simple.

The Commerce wagon was developed in a very simple manner. The first machines built were sold in Detroit and worked where they could be carefully observed and later on a selling organization was created in different sections of the country. To-day the company has agencies in many places where the machines are used, and owners have been given satisfactory attention at all

times. The friction transmission of power has been amply demonstrated to be efficient, and the

claim is made that Commerce machines have climbed grades of 60 per cent., which is far greater than would ever be attempted by any operator. The power plant has been continued after an experience of three years, it having been found equal to every requirement.

The motor is a Northway production, a four-cylinder, water cooled, L head type, with the cylinders cast in bloc. The casting is an excellent quality of fine gray iron and is cast with the water jacket integral, the entire length of the water jacket being open, this permitting careful clearing of the spaces. The entire block is covered with a cast plate, in the centre of which is the large water outlet manifold. The plate is retained by a series of cap screws. The upper half of the crankcase is cast with the cylinders, and this carries the three main bearings, these being of ample length. The lower half of the crankcase contains the oil reservoir and the web in which the oil is collected for the splash lubrication.

The rear supporting arms of the motor are wide and are webbed to afford strength, but the forward end of the engine is carried on a forging bolted to the forward end of the upper section of the crankcase, this forging being pivoted at the centre so as to afford a three-point suspension, eliminating all stresses from chassis distortion. The base of the motor may be removed readily for examination of or work on the main or connecting rod or camshaft bearings. The cylinders have a bore of three inches and stroke of 4.5 inches, this having a rating of 14.2 by the S. A. E. formula, but the engine is claimed to develop in excess of 20 horsepower because of the bore to stroke ratio of 1:1.5. The valve mechanism is protected by cover plates that are retained by studs and nuts, these being accessible and convenient when removal is necessary.

Combination Lubrication System.

The motor is lubricated by a combination of force feed and splash, the oil being drawn from the reservoir by a plunger pump that is driven by a worm mounted on the camshaft, the pump capacity being regulated by a screw and nut placed close to the filler

Top View of the Chassis of the Commerce Delivery Wagon, Showing the Friction Form of Power Transmission and the Extreme Simplicity of Construction.

The Intake Side of the Four-Cylinder, Water-Cooled Motor Used in the Commerce Delivery Wagon Chassis.

cap. By this pump the oil is forced to the main bearings and the timing gears, and the remainder of the motor is lubricated by splash from the sweep of the connecting rods in the pits in the pan in the bottom of the crankcase. The engine is cooled by a belt driven fan and a thermo-syphon circulation of water through the water jackets and the large radiator, there being a free flow of the liquid under all conditions of operation.

The ignition is by a Bosch magneto with a fixed spark. It is maintained that with this form of control the motor can be driven to capacity and the speed ratio varied as may be necessary without overworking or abusing it, and that the engine cannot be made to knock or pound, no matter what the demand upon it. The carburetion is by an automatic float feed type that is said to afford a satisfactory mixture at all engine speeds.

The flywheel carries a fixture into which the forward end of the driving shaft is fitted, this end telescoping slightly. This end of the shaft is rectangular. The rear end of the shaft is carried in a large bearing mounted on the centre cross frame member. This member is strengthened by braces and gusset plates. The bearing maintains the alignment of the shaft and on the rear end of the shaft is coupled the driving wheel, this being a heavily ribbed disc with a face smoothly finished. The wheel has a slightly longitudinal movement in the chassis, this movement being controlled by a pedal. This driving wheel always revolves at engine speed.

Friction Transmission.

Mounted on a cross shaft that is carried in heavy bearings on stout brackets is the driven wheel or disc, the centres of this shaft and the main driving shaft coinciding. The driven wheel can be moved transversely in the chassis frame on the shaft for the full diameter of the driving disc. The rim of the driven wheel is faced with a sectional ring of fibre. The driving shaft and driving wheel may be moved longitudinally and either contacted with or removed from the driven wheel. The driven wheel may be located at any point within the range of movement on the splined jackshaft. When placed between the centre and the

left edge of the driving wheel the normal forward motion of the chassis is obtained, and when placed between the centre and the right edge of the driving wheel (right and left being with reference to the driver's position in the seat) the reverse of the motion is located. The speed of the driven wheel is entirely dependent upon its position between the centre and the edge of the driving disc, and it may be any ratio desired, minimum at exact centre and increasing until maximum is attained at the outer edge. With position the same at either side of the centre of the driving wheel the reverse or forward motion of the jackshaft is identical, and for that reason, and the fact that reverse is not desired to be fast, the extreme reverse position is approximately but a third of the radius of the driving disc.

The movement of the driven wheel is controlled by a hand lever that may be set by a dog that meshes with a notched quadrant and released as desired by pressing a release incorporated with the grip of the lever. Power is transmitted from the jackshaft to the rear axle by a chain that is fitted to sprockets, the one on the jackshaft and the other in a housing containing the differential gear in the axle, the differential being supported and protected by a heavy spider. The axle is strengthened by truss rods. The rear axle is a live type with the shafts carried in housings on large roller bearings.

General Chassis Details.

The chassis frame is a four-inch pressed steel channel section having five cross members, one forward of the motor, the second supporting the forward end of the engine, the third carrying the main driving shaft bearing, the fourth back of the jackshaft, and the fifth at the rear end, each having large gusset plates and reinforcements. The frame is supported on semi-elliptic springs, the rear set being outside of the frame and shackled at either end. The drive is through adjustable radius rods. The forward axle is tubular, having specially reinforced steering knuckles and arms. The wheels are artillery type, 12 spokes, and either

The System of Friction Power Transmission of the Commerce Wagon, Showing the Driving Disc and the Driven Wheel, Jackshaft and Chain.

32 by 3.5-inch quick detachable pneumatic or 34 by 2.5-inch solid tires are installed at option of the purchaser, the former being advocated by the maker. The drag link is fitted with double springs at either end and the steering gear is an irreversible worm and split nut type. The drive is left side with a throttle lever on top of the hand wheel. The movement of the driving wheel and the operation of the service brake are obtained by operation of pedals, the brake being applied by expanding shoes in drums on the rear wheels. The reverse of the driven wheel is used for emergency braking.

Much care has been taken to insure endurance. Hyatt roller and New Departure ball bearings are used throughout, with large ball thrust bearings where necessary, and ample provision has been made for lubricating all wearing parts. The fibre ring face of the driven wheel can be removed and replaced in a half hour at a cost of \$3.75 for material. These will endure from 3000 to 12,000 miles in service. The driving chain may be adjusted conveniently when needed.

The chassis is equipped with four body types by the makers, these being an open express with flare boards, express body with standing top enclosed by curtains, a full panel body with rear doors or end gate, or a stake platform. With the standard bodies the loading space is 64 inches length, 42 inches width, and with the enclosed bodies the height is 52.5 inches. The tail gate is 22 inches height. The wheelbase of the chassis is 102 inches and the speed is from 15 to 20 miles an hour, as may be recommended by the maker.

The driver's seat will accommodate two persons. The chassis are fitted with fenders and running boards, a tool box being carried on the left running board. The equipment includes dash and tail combination oil and electric lamps, windshield, electric horn, storage battery, pump, jack, kit of tools and tire repair outfit.

The working force of the Goodyear Tire & Rubber Company, Akron, O., has been increased from 6500 to 8000, the addition being necessary by the growing demand for the products of the company.

In January the working force of the Peerless Motor Car Company, Cleveland, O., was increased about 500. The company expects to considerably increase the production of its truck department.

More than 100 motor wagons and trucks were placed in service in Manitoba during 1913, and it is believed that this number will be considerably increased during the present year.

EDUCATE THE BUYER.

One fault that can be accredited to practically every motor vehicle salesman, and in this the responsibility primarily rests upon the manufacturer of wagons and trucks, is the assumption that a purchaser can utilize a machine to its greatest value. As a matter of fact very few men, especially those who purchase one or several units, can grasp the necessity of using their equipment every minute that is possible, and those who do realize this need are generally handicapped by methods that were used with horses.

Many instances have been noted where the owners of machines failed to obtain anything like the service that was practical, if ordinary thought were given to the work. Most men will gratefully accept advice, but rules cannot be generally applied, and for this reason attention must be given to any particular work and principles adapted. Salesmen cannot be expected to have qualifications that fit them for supervision, but it would be possible for a man with broad knowledge

Commer Delivery Wagon Chassis Fitted with a Standard Type of Body Adapted to the Service of a Grocery Dealer.

to make suggestions that would be helpful, and to assist in making such changes as would be desirable or necessary to obtain the fullest benefit of the machines.

The Sternberg Manufacturing Company, Milwaukee, Wis., has increased its capital to \$250,000 from \$100,000. The factory has been increased by an addition 150 by 100 feet, and with the facilities it now has the company is prepared to build 225 vehicles this year, this being an increase of about 50 per cent. of the 1913 production. The company is about to build a 2.5-ton vehicle that will have a worm drive.

The agency for the Wagenhals delivery wagons has been established with the M. C. M. Company, Cambridge, Mass.

Frank L. Roberts & Co., Boston, Mass., has been made agent for Velie motor trucks.

ADAMS TRUCK DESIGN STANDARDIZED.

THE Adams Bros. Company, Findlay, O., is now building three sizes of service wagons, these being of 2000, 3000 and 4000 pounds capacity respectively, and these are constructed practically to the same design, there being variance only in the dimensions of the components, and, of course, the completed chassis. The company has been engaged in manufacturing for many years and its policy has been always conservative. In building machines the purpose has been to produce only what can be regarded as thoroughly dependable, and the designs have been carefully tested and tried to prove dependability and endurance.

The company has standardized its constructions and has produced machines that are adapted for service in widely differing conditions, there being abundant margins of safety, sufficient power for all requirements, and the material has been carefully selected. The selling organization of the company has been developed with much care and wherever the agencies have been established the attention given to the users of Adams trucks has been such as to insure satisfaction and continuance of service.

The vehicles are constructed of high class material. For instance, the motor is a Continental, the jackshaft and transmission gearset are a Warner construction, the axles are Timken, the steering gear is a Ross, the universal joints are Spicer made, and these components are incorporated with the purpose to obtain machines that are extremely simple, are accessible for examination or work, and the specialized parts can be depended upon from every point of view.

The Continental motors used are a block, water-cooled, four-cylinder, L head type, that of the 2000-pound wagon having a cylinder bore of 3.75 inches and stroke of 5.25 inches, which is rated by the S. A. E. formula at 22.5 horsepower, and is conservatively claimed by the maker to develop 30 horsepower. The motors for the 3000 and 4000-pound wagons are identical, having cylinder bore of 4.125 inches and stroke of 5.25 inches, these being similarly rated at 27.25 horsepower, but claimed by the maker to develop 35

horsepower. These engines are standard productions and are widely and favorably known. They are regarded as developing their maximum capacity at 1000 revolutions a minute. The motors are carefully tested and are sent out with the guarantee of the maker that they are factory perfect and reliable from the viewpoint of service.

The cylinders and pistons are carefully made, the crankshaft and camshaft are large and are carried in ample bearings, the connecting rods are generous in size, and the bearings are constructed with a view to securing long wear. The valve mechanism and the timing gears are designed to endure long service without material wear and the valves are enclosed to insure protection against abrasion. The motor bearings are of nickel babbitt carried in bronze cages. Accessibility is carefully provided for, and work can be done with the minimum of time. The motor lubrication is by a circulation of oil drawn from a reservoir in the base of the crankcase and carried through a sight feed gauge mounted on the dash and thence distributed by one lead of tube to the timing gears and by the other to the rear main bearing. A positive driven plunger pump carries the oil through the tube and the overflow is drained from the rear main bearing and the timing gear case to pits in the bottom of the engine case, into which the big ends of the connecting rods sweep. This insures effective lubrication of all the moving parts of the motor, and the oil in excess of the requirements of the pits flows into the reservoir and is filtered before it is again circulated.

The engine is cooled by a circulation of water, a large pump of the centrifugal type, driven by an outside shaft, forcing it through the liberal water jackets and a vertical tube radiator that is located back of the motor and incorporated with the dash. The radiator is cooled by a draft of air caused by the fan-bladed flywheel during the time the engine is operating. The radiator is a vertical tube construction and it is mounted on flexible supports so that it is not affected by the movement of the chassis frame. This location affords full protection for the radiator and permits free access to the motor from sides and front when the sloping hood of French type is raised. The ignition is by an Eisemann magneto with automatic spark advance that is controlled by the speed of the engine and requires no attention from the operator. This control governs the engine perfectly. The carburetor is an automatic float feed type that is economical of fuel and af-

Top View of the Ton Chassis, Built by the Adam Bros. Company, Findlay, O.

fords a satisfactory mixture at all engine speeds.

The clutch is a dry disc construction that is always positive in operation and engages easily. The engine and clutch are mounted in a sub-frame that is so supported that the power plant is not affected by the stresses of the chassis frame, and this frame carries the shafts of the centre control levers. The main driving shaft has two universal joints between the clutch and the gearset. The gearset and the jackshaft are assembled as a unit, the gearset being a sliding gear selective construction, having three forward speeds and reverse, and the case is supported at three points. The jackshaft is floating, the outer ends being carried in sturdy hangers that give certain support, and on the shafts, inside the chassis frame, are the 10-inch drums with three-inch faces of the service brake.

The chassis frame is a pressed steel channel section five inches width, and this is built with numerous cross members and sturdy gusset plates and braces. The forward end of the frame is "necked" to permit full swing of the wheels in steering. The springs are semi-elliptic throughout. The forward axle is an I section and the rear axle is rectangular, both being of ample proportions. These are fitted with 36-inch diameter wheels for all machines, and the regular equipment is with demountable tires. The drive is at the left side and the steering gear is an irreversible type with a large hand wheel. The control levers are at the centre, at the right of the driver. The fuel supply is controlled by a foot accelerator. The emergency brake is operated by hand lever, the shoes expanding within drums 13.5 inches diameter and 2.5 inches width on the rear wheels, and the service brake bands contract on drums on the jackshaft, being actuated by a pedal. The bearings of the transmission gearset and the differential are F. & S. ball construction, and the wheels are fitted with Timken roller bearings throughout.

In these general characteristics the machines do not vary aside from dimensions or proportions of components. The 2000 and 3000-pound vehicles are built with 121 or 136-inch wheelbase, and tread of 56 inches, at the option of the purchaser, and the 4000-pound machine has wheelbase of 140 inches and tread of 60 inches. The 2000-pound chassis has 3.5-inch solid tires forward and four-inch tires rear; the 3000-pound chassis 3.5-inch solid tires forward and 3.5-inch dual tires rear, and the 4000-pound chassis four-inch tires forward and four-inch duals rear. The lightest machine is governed to 15 miles an hour, the intermediate size to 14 miles, and the largest to 11 miles an hour in stock designs, but these speeds may be varied by changing the sizes of the sprockets. With the 2000

and 3000-pound chassis the maximum body length back of the driver's seat with 121-inch wheelbase is 108 inches, and with 136-inch wheelbase 132 inches. The 4000-pound machine has a maximum body space of 138 inches. The chassis is sold with a seat for the driver having capacity for two persons and upholstered in black leather. A single cushion is furnished, but a single or dual lazy back is installed at the option of the purchaser. The chassis is equipped with oil dash and tail lamps, horn, oil can, tool kit, set of wrenches and jack. Either long or short wheelbase chassis are furnished at the list price. Painting is done when required by the buyer at standard prices for the work.

REORGANIZING ITS FACTORY.

The Kentucky Wagon Manufacturing Company, Louisville, Ky., which builds the Urban electric wagons and trucks in addition to an extensive wagon and carriage production, has completed the reorganization of its manufacturing and selling departments with the purpose of greater efficiency and economy. The changes have not reduced the productiveness of the plant, but have consolidated departments and better directed endeavors, and the result is expected to be a considerable increase in business.

A body building department has been established in the factory of the Buffalo Electric Vehicle Company, Buffalo, N. Y., which is in charge of E. E. Deniston, and which is now prepared to design, construct, finish, repair and restore vehicle bodies of any description. The company will build a line of stock bodies, but will produce special work to the specifications of those who desire it.

After a connection with the company for 11 years, E. F. Russell, factory manager for the Locomobile Company of America, Bridgeport, Conn., has resigned that position and will take a rest before associating himself with another enterprise. Mr. Russell has not decided his future plans.

Two-Ton Adams Truck in the Service of the American Bed Company, St. Louis, Mo.

ELECTRIC TRACTORS BIG ECONOMY.

Saving of More Than 50 Per Cent. Obtained by the Substitution of the Machines for Mules in Short Hauls of Timber in a Mammoth Louisiana Lumber Yard.

By A. L. Dixon.

YOU take the New Orleans Limited from New York to New Orleans, then the "midnight" over the Santa Fe to Lake Charles, La. Here you get a cup of coffee and perhaps a boiled egg before taking the local for Nitrim. From here you go to Elizabeth by auto, reaching there in time for supper at the one hotel in what is practically the heart of the yellow pine forest.

Most people would call Elizabeth nothing but a lumber camp and in some respects it is, but it contains one of the most up-to-date lumber mills in the South. Manager R. M. Hallawell and Electrical Engineer James Hill have made this an electrical plant throughout. They are firm believers in the "juice", and if there is no electrical apparatus on the market to do their work, they either make it themselves or have some manufacturers build it for them.

The plant of the Industrial Lumber Company has a daily capacity of about 300,000 feet, which means that it must cut over about 20 acres of land a day. Six large freight engines and 75 flat cars are used to move the logs in from forest to mill. About 1000 hands are employed, nearly 50 per cent. of these being negroes. Efficiency is the watchword from the felling of the trees to the moving of the lumber in the yards by the new electric "mules". Even the bark and stripings from the side of logs, which in most mills are carried to one end of the yard and burned, are at this mill run through a "hog" (a large electrically driven high speed cutter), which shreds the material, and

from here it is conveyed to turpentine boilers or vats, where the turpentine is extracted from the wood by a process of steaming. This is but one indication of efficiency.

Lumbering with Power Equipment.

The trees are sawed down, cut in half and then pulled from the forest to the side of the track by a huge steam derrick, which can pull four logs from four different directions at the same time. From the side of the track the logs are loaded on the freight cars by a mechanical loader which travels on the standard gauge track. The train of loaded cars is then run back to the mill, where the logs roll by gravity into the mill pond. From here they are carried to the mill by an endless chain system.

About 25 per cent. of the mill's output goes to the timber docks, where it is shipped abroad or to American users requiring heavy timber. The dry kilns take about 15 per cent. The lumber is piled on the stacks and put through a planer. The moving of this lumber required about 20 mules and a corresponding number of men, and it was to displace these that the electric tractor was built.

Description of the New G. V. Tractor.

While the tractor in question was not exactly a new proposition for the General Vehicle Company, this is the first time, to the writer's knowledge, that an electric tractor has been adapted to operating conditions of this kind. The general specifications called for something which would handle quickly from two to four tons of lumber; something which would load and unload very quickly and yet be simple in operation and inexpensive to operate, at least from the standpoint of labor. Freedom from fire risk was also a consideration. The requirements were met by building a tractor of the following specifications:

Chassis rating, two tons; battery, 44-17 G. V. lead; motor, General Electric 1026-85 V.; controller, S-35; wheelbase, 54 inches; frame, four-inch rolled steel channel; wheels, artillery type on Timken bearings; tires, front, 28 by four inch; rear, 28 by 3.5 inches, dual; counter-shaft, housed type on Timken bearings; brakes, internal ex-

Electric Tractor Equipment of the Industrial Lumber Company, Elizabeth, La., Used in Handling Stock in the Yard.

pansion on rear wheels; springs, half elliptic, front and rear.

As will be noted from illustration, the battery is mounted on the top of the chassis, the driver's seat is at the rear of the battery, the controller is at the driver's left hand, while the brake lever is operated by his right foot and the bell by his left foot. The cradle is supported by a steel extension from the chassis frame and rests on a substantial revolving block held to the supporting members by a king bolt which passes through.

The lumber is first loaded on the standard two-wheel lumber dolly and is connected to the tractor by backing the tractor under the lead, a chain being thrown around the lumber back of the first crossbar on the dolly and in turn attached to the end of a cable which passes through a guide bolt near the king pin and around the drum of a standard Sprague hoist. The driver presses a lever on his left and the hoist operates the cable which tightens the lumber to the dolly and holds it securely to the rear bolster.

In moving lumber from the mill to the lumber stacks, the tractor has a capacity of 7.5 round trips (2400 feet each) an hour, towing an average of 1500 feet of lumber, or 3.375 tons. In this work one tractor replaces five mules and three men.

Five Miles of Tramways.

This big mill has about five miles of tramways, which tramways run from the mill to all parts of the different yards. Tramways are from 16 feet to 20 feet wide and are floored with three-inch timber. At the mill the tramways are about 20 feet from the ground, sloping to about four feet at the opposite end of the yard. The lumber is worth \$13 a hundred board feet and costs \$5 a hundred for laying. These figures are important, as the mules' shoes necessitated the renewal of this lumber every three years at a cost of \$25,650. Obviously rubber tires will show a big saving in this item alone.

After the lumber is dried it is moved from the lumber stacks and dry sheds to the planing machines and then loaded into freight cars located from 60 to 1000 feet away, either by hand or by the tractor. This work is considered very hard on the mules and difficult for the truck as the hauls are very short and the roads tortuous. The truck has to go between the planers and in other narrow places and into the drying sheds, where it is necessary, sometimes, to back down a long narrow aisle. It is in this class of work that the tractor shows the largest saving, due to its flexibility of operation in the smaller spaces and that it may be loaded and unloaded quickly.

In such work one tractor displaces seven mules and five men, making 13 round trips per hour with 1100 feet of lumber a trip. The average distance covered a round trip is 2000 feet. In transferring lumber from the dry kiln to the dry sheds, work can be done with one tractor in two hours, that will usually take all day working a pair of mules.

The following analysis of the cost of operating with the G. V. electric lumber tractors and mules is of decided interest, the three tractors and six men doing the work for which 16 mules and 20 men were required.

Analysis of Operating Cost.		Mules	Tractors
Investment:			
16 mules at \$225 each.....	\$3,600		
20 sets harness at \$25 each.....	500		
20 two-wheel dollies with shafts at \$25 each.....	500		
3 electric tractors with (G. V.) batteries at \$2900 each.....			\$8,700
Stable, grain, horse, blacksmith shop, etc.	3,000		
Garage, charging apparatus, etc.....			1,000
Total.....	\$7,600		\$9,700
Fixed Charges:			
Interest	\$228		\$291
Depreciation	1,140		1,020
Fire insurance	100		87
Total fixed charges per year.....	\$1,468		\$1,398
Operating Costs:			
Renewals of batteries (every year).....			\$867
Renewals of tires (every year).....			600
Renewals of chains, gears, etc.....			375
Feed, shoeing, stable help, etc., at \$20 per month per mule (16 mules).....	\$3,840		
Labor at \$1.75 per day.....	10,500		3,600
Repairs to tramways.....	8,550		4,275
Total operating costs per year.....	\$22,890		\$9,717
Total costs per year.....	\$24,358		\$11,115
Saving per year by using electric tractors.....			\$13,243

No current has been figured in the operating costs of the three tractors as the amount used is not considered of any consequence. Assuming that a mill were to buy current from the central station at four cents a kilowatt-hour the cost of same would not average over \$200 a tractor, or \$600 in all.

Operating costs of tractors are given with G. V. conservatism, as the figures include battery, tire, gear and chain renewals each year. The load is towed, not

Mammoth Yard of the Industrial Lumber Company, Showing the Tramways and the Stock Piled in Grades of Quality and Size.

carried, and this should favor tires and other parts which show rapid depreciation in heavy haulage.

From the above it will be seen how that one special application of the electric commercial vehicle has resulted in a substantial saving to the manufacturer in question. It is an open secret that the tractor and the trailer offer many advantages in present day trucking, and I believe we shall see many more of these special applications of the electric.

POSTAL WAGONS DO GOOD WORK.

The first official statement as to the results obtaining with motorized vehicles in the service of the government postoffice department is contained in the annual report of J. A. Edgerton, purchasing agent for the department, filed with the postmaster-general at Washington. This report contains the following: "Heretofore all vehicles have been rented under contract. On Jan. 20, 1913, my predecessor issued an advertisement for motor vehicles and on March 3 an award was made to 13 contractors for an aggregate of 100 machines. This award was afterwards declared invalid by the controller on the ground that on the date mentioned there was no appropriation available out of which said purchases could be made. Subsequently a special committee was appointed to investigate and standardize vehicles for the service, being directed among its other duties to inquire into the relative cost of purchase and rental of motor cars. This committee reported favorably on the purchase of 41 machines, 20 being of the four-wheeled and 21 of the three-wheeled type. Such purchase was subsequently made. The investigation is still in progress.

"All of the four-wheeled machines are now in the service and while reports have been necessarily meager the indications thus far are that a marked saving will be shown as compared with cars under rental. This is especially true of motor cars employed in parcel post delivery".

The McIntosh & Seymour Corporation, with capital of \$2,200,000 has been organized to succeed McIntosh & Seymour Company, builder of steam engines, at Auburn, N. Y., and will build Diesel oil engines of different sizes for motor vehicles and stationary power plants. The company is made up of American and Swedish capitalists and the latter interests have the right to build Diesel engines in Sweden by the Hesselman system. The company has a strong engineering corps and it has affiliations with several large financial houses.

A building one story in height, 120 by 140 feet, of reinforced concrete, is being constructed at the plant of the Timken Roller Bearing Company at Canton, O., and will shortly be ready for occupancy.

G. P. Kurtz has been appointed agent at Washington, D. C., and Baltimore, Md., for Garford trucks.

WANTS OHIO LAW AMENDED.

The proposition has been made to the Ohio legislature by Governor Cox that the Warnes law, which has in part been declared unconstitutional, be amended so that the revenue received from the registration of motor vehicles in excess of the expenses of maintaining the registration bureau of the state, be placed to the credit of a fund to be devoted to the improvement of the state highways. The Warnes law provided that this surplus be transferred to the general fund, and this was the basis of the suit to test the constitutionality of the measure. The Ohio Automobile Association has assumed the attitude that the registration fees are in the nature of a tax rather than amounts sufficient to maintain the registration department, and any proposed change in the statute that does not make substantial reduction in the fees will be opposed in the legislature and later, if passed, will be fought in the courts.

New service stations have been established by the Eisemann Magneto Company with the Philadelphia Magneto Repair Company, 1429 Spring Garden street, Philadelphia, Penn.; H. G. Zimmerman, Linden and Walnut streets, Harrisburg, Penn.; P. Melchoirs Machine Works, 1218 Howard street, Omaha, Neb.; Archer-Wiggins Company, Sixth and Oak streets, Portland, Ore.; Storage Battery Service Company, 1525 Broadway, Seattle, Wash.; Bissinger's Magneto Exchange, 1611 Prospect avenue, Cleveland, O.; McCarthy Bros. & Ford, 41 East Eagle street, Buffalo, N. Y.; Auto Supply Company, 42 South Second street, Memphis, Tenn.; Charles Rehl & Co., 1312 14th street, N. W., Washington, D. C.

The Kentucky Court of Appeals, sitting at Frankfort, Ky., has declared constitutional the provision of the Kentucky state law that exempts from registration the vehicles of non-residents who pay registration fees or license taxes in the states in which they reside. This case was that of the City of Newport, Ky., against Merkel Bros. of Cincinnati, O., which used motor trucks in serving its customers in Newport and vicinity and refused to pay a license fee in Kentucky. When legal proceedings were instituted the company secured an injunction in the circuit court of Campbell county that prevented a fine being imposed by a police court judge pending a determination of the constitutionality of the law.

The Falls Machine Company, Sheboygan Falls, Wis., has begun the manufacture of a new model engine that is catalogued as "F", which is designed for hard service. It has small cylinder bore, long stroke and presents several distinctive features.

The Moreland Truck Company, Los Angeles, Cal., has appointed S. W. Merritt, formerly of Detroit, Mich., engineer of the production of its factory.

PHILADELPHIA NEEDS MOTORIZED EQUIPMENT.

Investigation Results in Recommendation for Immediate Purchase of Modern Fire Apparatus--- Municipal Garage Plan---Chicago Considers Street Conditions.

IF THE plans of George D. Porter, director of public safety in Philadelphia, are brought to a successful conclusion, manufacturers of motor fire fighting equipment will have a chance to bid on about \$600,000 worth of work. Mr. Porter has received the assurance of Chairman Connelly of the councils' finance committee that the appropriations requested to put the fire department upon an up-to-date basis, in point of equipment and other necessary features, will be passed without objections from the councils.

Director Porter states that after 15 months of careful and detailed investigation, he is compelled to report that the Philadelphia fire department is in an antiquated condition, and that it is from five to 10 years behind that of many other cities. He maintains that \$2,870,000 is needed to modernize the department and bring it to an equal footing with others.

The director further recommends that 34 of the old style fire engines be replaced immediately by motor driven pumping apparatus. He shows that the need for these engines is acute, and estimates the cost of this equipment at \$350,000. The total value of the apparatus now in use is placed at \$246,933.50, of which the motor driven equipment is represented by \$66,189. There are 17 motor vehicles now in service, and 11 others have been contracted for at a cost of \$58,000. These latter will be delivered within the near future.

There are 16 aerial trucks, of which one is of modern construction. Of the large number of combination hose wagons, nearly all are reported in bad condition and only two are motorized. There are 14 fuel wagons, or tenders, all of which are horse drawn and the majority are held to be beyond repair. Director Porter has recommended that these be replaced by eight motor trucks.

Police Patrol for Portland—The police department in Portland, Me., has taken possession of its new patrol wagon, the chassis for which was made by the Pope Manufacturing Company, Hartford, Conn. The body work was by the Soule-Smith Company of Portland. The equipment includes a stretcher, medical and surgical outfits, etc. The first machine, which was of the same make, was purchased three years ago

and has covered 27,000 miles in service and has given excellent satisfaction in every respect.

WANTS MUNICIPAL GARAGE.

Mayor of Worcester Has Interesting Plan for Handling City's Automobiles.

Mayor George M. Wright of Worcester, Mass., in his annual address before the city government took occasion to recommend the establishment of a municipal garage, to house all of the automobiles owned by the city departments with the exception of those used by the police, and possibly the emergency cars of the water department. His plan is somewhat novel in several respects.

He holds that municipal automobiles should event-

Knox-Martin Tractor Attached to Hook and Ladder Truck in Service with Philadelphia Fire Department.

ually be standardized to not more than three or four makes, one for five passengers, one for medium weight and one for an inexpensive light car, all being adapted to the work of the superintendents, inspectors and foremen, as well as for viewing by committees of the city council. These cars, he feels, should be available at all times, and should be kept in a modern garage, owned by the city, and cared for in the most businesslike manner.

In establishing a municipal garage, he desires that all automobiles be marked "City of Worcester", and numbered. None of them is to be assigned to any particular department. They are all to be for the use of any department which may need them, and for such use each department is to be charged at an hourly rate as nearly as possible at cost.

The mayor holds that there are many advantages

in the plan, chief among which are: The employment of experienced repair men and drivers, the purchase of supplies at a reduced rate, and a general improved efficiency. He believes that the purchase of supplies in bulk, repairs made by the city repair shop and the gradual supplying of cars of uniform type with interchangeable parts, as the present cars outlive their usefulness, will result in the saving of many dollars of the taxpayers' money.

STAMFORD'S MOTORS EFFICIENT.

Saving in Property Losses Sufficient to Pay for Investment Many Times Over.

With the investment of \$25,000 for motor driven fire fighting equipment during the past three years, the city officials of Stamford, Conn., believe that they have placed the fire department in that city on the list of the most efficient in the country. In addition,

Tank Wagon Supplied by Martin Carriage Works for Street Sprinkling in Lebanon, Penn.

it is maintained that the machines have been enabled to save property loss sufficient to pay their original cost many times over.

The equipment of the department consists of a Locomobile combination chemical and hose wagon, purchased in May, 1910; an American-La France pumping engine, purchased in November, 1911; a Pope-Hartford chief's car, and a second American-La France pumping engine purchased last year.

In 1910 the Locomobile machine answered 100 calls, in 1911 154, in 1912 159 and in 1913 111. During the past year it was withdrawn from service for a complete overhaul at a cost of \$1000. The first pumping engine was called upon to work all night in freezing winter weather soon after it was installed, and was as fresh as ever when called to answer an alarm the next day. In 1912 it answered 90 alarms and, in 1913, 66. The experience with these two machines is held to have been such as to justify the purchase of the two added last year.

MARTIN STREET SPRINKLER.

Chassis Details of Equipment Recently Produced for Service in Lebanon, Penn.

An accompanying illustration presents the tank wagon recently supplied to the Rescue Hose Company No. 4, Lebanon, Penn., by the Martin Carriage Works, York, Penn. This is designed for sprinkling the streets and provision is made for operating the sprinkling apparatus from the seat. The construction follows standard principles throughout and the completed vehicle presents an attractive appearance.

The equipment is installed on the regulation model E chassis produced by the Martin concern, which has a rated load capacity of 4000 to 5000 pounds. The motor is a water-cooled unit of the T head type, with bore of 4.25 inches and stroke of five, giving a rating of 28.9 horsepower under the S. A. E. formula, although the maker claims it will develop 35. Lubrication is by gear pump.

The clutch is a multiple disc, and the transmission is a Brown-Lipe built in a unit with the Timken jackshaft. Final drive is by chain. The rear axle is a Timken-Detroit, rectangular, 2.25 by 3.625 inches, with 2.75-inch spindles. The front axle is an I beam, 2.25 by 3.375 inches, with 2.125-inch spindles. The springs are semi-elliptic all around, those in front being 42 inches long by 2.5 wide and the rear members being 50 inches long and 2.75 wide. Two sets of brakes are fitted, the service on the jackshaft and the emergency on the rear wheel hubs.

The frame is of structural steel channel with wood insert, well braced and bolted together. The wheels are of wood, fitted with 36 by four-inch single tires in front and 40 by 3.5-inch dual in the rear. The wheel-base is 135 inches and the tread is 61 inches in front and 65 at the rear. With full load over hard, level roads, the speed is held to be 15 miles an hour. The driver is at the right.

Motorcycles in Fire Service—A number of firemen throughout the country are utilizing motorcycles in answering alarms. A notable example is the department in Fresno, Cal., one company of which is well supplied with these machines. Chief H. L. Stanton, Norwich, Conn., finds a motorcycle with sidecar attachment a very satisfactory vehicle, in that it places him at the scene of the blaze ahead of the other members of the department. The two-wheel mount has been used with success in many foreign countries.

REPORT INDORSES TRUCKS.

Investigation of Street Conditions in Chicago Reveals Their Advantages.

Following an investigation, lasting from April 21 to Oct. 13, 1913, the commissioner of public works and the civil service commission of Chicago have placed before the city council an interesting report concerning the street department. As a result, it is recommended that provision be made in 1914 for the purchase of at least two five-ton trucks for hauling crushed stone and material for street repair work and the use of motor driven vehicles in street cleaning work.

The report finds that every 100 horses litter the streets and alleys of the city with one ton of refuse during a working day of eight hours. This amounts in the course of a year to 493,934 cubic yards, or about 50 per cent. of all the refuse annually removed from the city streets, exclusive of garbage and ashes. Carrying out the argument, the report states that the total cost of removing street rubbish during 1912 was \$1,916,217; therefore, if 50 per cent. of the refuse is attributable to horses, the city would be some \$1,000,000 richer if there were no horse drawn vehicles.

Several important conclusions may be drawn from the facts given: First, that the substitution of motor vehicles for horse drawn vehicles would reduce the cost of street cleaning, lessen the wear of street pavements and help materially to decrease the city death rate; second, the use of motor trucks by the street cleaning department would effect further savings in cost of street cleaning and ash and garbage disposal; third, that the elimination of horses would preserve street pavements, and fourth, that replacement of macadam pavement by more permanent pavement would lower the cost of street cleaning and maintenance.

Referring to street repairs, the report makes the important observation that "where the cost of repair and maintenance is equal to or even greater than the annual interest cost on new work, it is more desirable that new pavement be laid wherever possible." The average cost of repairing and improving 55 miles of macadam country roads within the city limits is estimated at \$750 a mile. This represents six per cent. interest on \$12,500 a mile.

In a section of the report devoted to motor trucks, there is an analysis of the relative cost of hauling by horse drawn vehicles and motor trucks or tractor. A table prepared by R. T. Dana, member of the American Society of Civil Engineers, shows savings by self-propelled vehicles ranging from four per cent. for hauling two miles with load, to 14.7 per cent. for 10-mile hauls.

Toledo Issues Bonds—In order to motorize its entire fire department, the city of Toledo has sold to the banking house of R. L. Day & Co., Boston, \$200,000 of bonds. It was at first intended to motorize the depart-

ment gradually and to pay for the change from the regular budget, but the council finally decided to issue bonds for the purpose. No definite plans have been made public concerning the steps to be taken in supplying the necessary machines, but with the funds now available for the purpose it is assumed that bids will be opened for several new pieces of apparatus in the near future.

NOVEL CONTRACT PLAN.

Pierce-Arrow Machines Win Award in Recent Contest Evolved in Chicago.

In order to forestall any criticism of impartiality, the bureau of engineering of the department of public works in Chicago adopted a new method in awarding the contract for four trucks purchased recently. Twenty truck salesmen were invited to submit vehicles to be judged on the following basis:

General:	Points
Price	10
Service facilities	9
Inspection and testing of parts and material.....	7
Results of test run	5
Responsibility of manufacturer.....	9
Comparative cost of repairs.....	4
Design and construction:	
Motor	12
Clutch	4
Transmission gearset	4
Final drive	10
Axles	5
Frame	5
Springs	3
Wheels and size of tires.....	5
Brakes	4
Steering gear and arrangements.....	4
Total.....	100

Under this plan the lowest bidder was marked 10 points, and the other bidders in inverse ratio to their price. The test run covered 53.4 miles in a specified time, and this included about two miles of very muddy road. The inspection included a thorough technical examination of the whole mechanical construction, also of the gasoline and oil consumption and other items entering into the cost of operation, and was made by a technical board not in the employ of the city.

As a result of this plan the contract was awarded to H. Paulman & Co., Chicago agent for the Pierce-Arrow Motor Car Company, Buffalo, N. Y., maker of Pierce-Arrow worm driven trucks.

In the Market—The following cities are considering the purchase of motor driven fire fighting equipment: Sheboygan, Mich.; Harrisburg, Penn., appropriation of \$25,000; Auburn, N. Y., Chief E. J. Jewhurst recommends additional apparatus; Middletown, N. Y., appropriation of \$8500; Holley, N. Y., combination wagon; Wheeling, W. Va., mayor agrees with Chief E. T. Rose in urging that department be motorized; Pecos, Tex.; Ithaca, N. Y.; Rochester, N. Y., 85-foot aerial ladder; Middletown, N. Y., combination wagon; Auburn, Cal., combination wagon.

STREET TRAFFIC CONDITIONS IN LONDON.

Effect of Motor Vehicles and Tendency Toward Congestion---Trucks Play Important Part in Recent Belgian Show---General News from Foreign Countries.

CONSIDERATION of traffic conditions has been carried somewhat further in foreign countries than in America, if full credence be given to the statements emanating from the large centres. Those who have had opportunity to study the situation maintain that the traffic of London is regulated more carefully than anywhere else in the world. This is the result of necessity, in a measure, since London is the largest city in the world, and even casual knowledge of the congestion existing in other large cities would suggest that special steps must be taken to prevent such congestion as would mean total inability to traverse the streets.

It is assumed that approximately 250,000,000 journeys were made during 1913 on the trunk railway lines within the metropolis of London. The local railway companies supply figures which necessitate the

local additions and improvements, is practically identical with that of a century ago—more especially with reference to the main roads radiating out of London. It is largely due to the introduction of the more rapidly moving mechanically propelled vehicle that it has been possible for this increased traffic to pass through the streets in their present condition.

London has recognized that the monetary loss to the commercial world is of importance, to say nothing of the number of accidents to persons in the streets. The people of London have not been content to await the activities of the authorities in the matter of bettering conditions, and, among others, the traffic branch of the Board of Trade has been engaged for six years in taking a tariff census, by means of which it has been possible to determine many points at which congestion is likely to occur. As a result of this annual census it has been found that the liability toward congestion is becoming more accentuated each year. At present this traffic branch is at work upon a scheme for diverting traffic from these danger points.

But, while the introduction of motor vehicles has had a tendency to prevent congestion, on the one hand, it has been the means of adding to the possibilities in this direction on the other, from the fact that there has been gradual withdrawal of a large amount of traffic from the railways to the roads, as the economy of this type of transportation has

been appreciated. Ninety-four per cent. of the passenger vehicles met in London are motor propelled. As yet, only 12 per cent. of the so-called trade vehicles are of this type, but there is a general consensus of opinion as to their practicability and utility, and the gradual extension of their adoption to the exclusion of the horse drawn vehicle is regarded as well assured in all directions.

An accompanying diagram presents the comparative results between the 1912 and 1913 census of the traffic branch of the London Board of Trade, and shows the gradual increase in the number and volume of motor driven vehicles. The report covers this matter in detail, and careful study of the diagrams will reveal all the information contained therein. These charts and the report will be laid before the London

A Section of Regent Street, London, England, Indicating Character of Traffic and Method of Handling It.

addition of 436,492,548 more. The tramways and omnibuses can account for 1,349,109,979. This information takes into consideration only passenger carrying vehicles of a quasi-public character, and shows that practically 66 per cent. of such traffic is by road. Of course, it is impossible to secure information regarding the number of journeys made by private vehicles or those made by freight wagons and trucks.

The number of passenger journeys made by road within metropolitan London has almost doubled within the last decade, and the increase in population and the growth of trade have brought, at least, a corresponding increase in the use of the streets by postoffice and railway vans, and by the express and freight handlers generally. In spite of all this additional traffic, however, the road system, with the exception of

city councils, together with other information respecting congestion centres, etc., in an effort to still further solve the problem of diverting the large volume of traffic through the streets with safety both to passengers and pedestrians.

POSTAL WAGONS IN GERMANY.

Four Cities Now Using Motor Equipment, Largely of the Electric Type.

In a recent issue particular attention was drawn to the electric vehicles utilized by the postoffice at Vienna, Austria. The German government also has a number of motor vehicles, largely supplied under contract, the principal cities in which they are operated being Berlin, Munich, Leipzig and Hamburg.

Berlin has a fleet of 73 machines, 19 of which are electrically propelled three-wheel vehicles with capacity of about 500 pounds. These are utilized in collecting mail from the street boxes and for carrying mail between the main office and the sub-stations. The next division comprises 13 three-wheel wagons of about 900 pounds capacity, which are used for parcel post delivery. Then come 35 four-wheel electric wagons of 3700 pounds capacity, used for transporting mail in bulk between the railway stations and the several offices. And lastly, there are six 20 horsepower, one-ton gasoline wagons for long distance work.

In Munich the machines are owned by the state and are housed in a garage in the suburbs. The fleet comprises 12 of the smaller three-wheel electric vehicles and 49 gasoline vehicles rated at 20 and 30 horsepower. The former are used as collection wagons and the latter for parcel post matter.

Leipzig has 26 electric vans of 3500 pounds capacity, supplied by a contractor, and these are used mostly for the transportation of parcel post matter, and mail in bulk. Hamburg has but one gasoline machine rated at 12 horsepower, and with carrying capacity of about 450 pounds. This is an experimental machine, utilized for making box collections. The postoffice officials at Hamburg experimented with electrics in 1908, but they were abandoned, it is claimed, because local conditions among which were the gradients, were held to be unfavorable.

TRUCKS AT BRUSSELS SHOW.

Two Belgium Concerns Make Display, One Presenting Knight Engined Model.

A special section of the annual automobile show in Brussels, Belgium, Jan. 10-17, was devoted to commercial vehicles, this being the first time in the history of that event in which such prominence has been given to this line. King Albert visited the display and spent some little time among the motor trucks and business wagons.

The business men in Belgium have been giving unusual attention to motor driven equipment during the past year. One or two makers displayed trucks at the 1913 exhibition, but these were not segregated, and little attempt was made to call special attention to them.

The truck exhibits this year were largely confined to machines made in Great Britain, Germany and France, but two Belgium makers were represented. One of these was the maker of the Minerva, which presented a 2.5-ton truck, fitted with a four-cylinder Knight motor of 85 mm bore and 140 mm stroke (3.3 by 5.5 inches), located in the cab. The transmission affords four forward speeds and reverse and the final drive is by shaft to a worm driven rear axle, of the overhead worm type. The Pipe concern also revealed a new 3.5-ton chassis of conventional design.

Results of 1912 and 1913 Census Presented Diagrammatically to Show Relative Increase in Various Types of Vehicles.

DAIMLER-KNIGHT TRUCKS.

Original Producer of Machines Utilizing This Engine Adds New Models.

So much interest has been created in the Knight type of sliding sleeve valve engine, because of the recent remarkable test of a Moline-Knight motor in the laboratory of the Automobile Club of America, New York City, that attention may be directed to the latest Daimler truck chassis. So far as is known, the Daimler Company, Coventry, England, was the first concern to produce a Knight engined commercial vehicle. This was about a year ago, the chassis being rated at one ton.

It was anticipated that this concern would be confronted with a certain amount of prejudice against the use of this type of power plant, but the success which it had attained with Knight engined pleasure vehicles was such as to indicate similar results in the new

which is the same as that of the S. A. E. in this country.

Both machines are fitted with large diameter cone clutches, and the selective sliding gear transmissions afford four speeds forward and reverse. Final drive is by shaft, fitted with leather disc universal joints, to a worm driven rear axle. Another feature of the new chassis is the use of what is termed in Great Britain, flitch framing, in which both the side and cross frame members are of wood encased in steel.

GENERAL NEWS FROM ABROAD.

Rice Transport in India—Announcement is made that the proprietors of several rice mills in India have been making inquiries with regard to the use of mechanically propelled vehicles for hauling rice long distances.

Tunis Agricultural Trials—The officials of the Tunis government have arranged for a trial of agricul-

Two-Ton Daimler Truck Chassis, Equipped with Four-Cylinder Knight Engine and Worm Driven Rear Axle.

field. In this respect it is said to have been demonstrated to the entire satisfaction of the officials during the past year that the Daimler-Knight motor was well adapted to this work. A number of Daimler omnibuses, thus equipped, have been operating in London and in other important centres in that country and abroad, and several wagons have been working on all kinds of roads and in the hands of skilled and unskilled drivers. Other concerns are now engaged in the production of trucks fitted with sliding sleeve valve motors, notably Argylls, Ltd., of Alexandria, Scotland, which utilizes the Argyll single-sleeve type.

For this year the Daimler Company has added two Knight engined chassis, one being rated at two tons and the other at five. In essential characteristics they are very much alike, except, of course, for the difference in dimensions to provide for differing carrying capacities. Both motors are of the four-cylinder type, the larger having bore of 110 mm and stroke of 150 (4.3 by 5.9 inches), and the smaller, 95 by 125 mm (3.7 by 4.7 inches). The former is rated at 30 horsepower, and the latter at 22.4, under the R. A. C. formula.

tural motors April 15-22. For the first time classes will be provided for implements propelled by electricity, the other classes being for gasoline, benzol and steam. Makers may enter any number of machines, but only one of each type, by addressing the Direction Generale de l'Agriculture, 76, boulevard Bab Benst, Tunis, North Africa.

Motor Plows and Tsetse Flies—According to the Usambara Post of Zanzibar, the cotton growers in the Kilimanjaro district of German East Africa are convinced that they must abandon the enterprise unless they are able to secure motor plows. The tsetse fly prevails in many parts of the country and interferes sadly with the use of animals.

Passenger Service in Tasmania—Reports from Hobart, Tasmania, indicate that a splendid real estate boom has followed the introduction of motor omnibuses on the Bellville-Richmond route. Several people have purchased homes in that district, depending upon the motor vehicles for transportation.

THE A B C OF MOTOR TRUCK IGNITION.

Part XVIII--Explaining the Construction and Operation of the Type N B Pittsfield Magneto, a True High-Tension Instrument Employing a Stationary Winding and Operating on a Distinctive Principle.

By C. P. Shattuck.

IN PREVIOUS installments the inductor type of magnetos was discussed, two forms being described and illustrated, namely the K-W and Remy instruments. These differed in that one was productive of a true high-tension current, while the other generated a low-tension. The K-W comprises two stationary windings, one of coarse wire (primary) and the other of fine (secondary), these being mounted between two halves of a rotor which revolved, but the windings remained stationary. The principle employed in the Remy

Fig. 103—Rear View of Pittsfield N B Magneto.

was similar (the Remy Electric Company has abandoned the inductor type), but the electricity obtained by the rotation of the inductors was low-tension. With the types mentioned it will be remembered that the winding, or windings, was mounted on the armature shaft of the instruments.

How Pittsfield Differs.

The type N B Pittsfield magneto differs materially from the types above mentioned, although the induction method is employed. By referring to Fig. 106, a longitudinal sectional view of the magneto, it will be noted that while the usual primary and secondary windings are utilized they are not incorporated with the armature, but are at the rear of the instrument, and are stationary.

The view at the right is a lateral cross section of the magneto and it will be seen that the field has four pole pieces instead of the conventional two. Two of the pole pieces are attached to the permanent magnets in the usual manner. The others with the iron core of the transformer coil (the primary and secondary windings) comprise the magnetic field in which the armature or inductor rotates on ball bearings.

Alternating Current.

The rotation of the inductor in the magnetic field serves to reverse the flow of magnetism alternately from the pole pieces to the magnets forming a magnetic circuit with the transformer coil core. This al-

ternating current, during each revolution of the armature, attains a maximum four times, and with each 90-degree rotation of the armature a spark is obtained. With the type N B Pittsfield only two sparks are utilized.

Primary Winding.

One end of the primary winding of the transformer coil is connected to a contact button which is at the left of the horizontal bar above the circuit breaker mechanism and is depicted at Fig. 105, this being a rear view of the N B instrument. The other end of the primary is attached to a contact plate incorporated in the horizontal bar referred to, which is screwed onto the field, and insulated from it by a hard rubber plate and bushings. A brass plate forms a connection for the passage of the primary current to the platinum contact piece and contact screw. This plate is shown in the illustration detached from the platinum contact screw retaining mechanism, as the circuit breaker cover has been displaced. This plate, or lever as it may be termed, moves with the circuit breaker housing.

Interruption of Primary Circuit.

The contact piece is insulated from the interrupter plate, which is in metallic connection with the field or ground. The platinum contact points are normally held together by means of a spring. The lever is in metallic connection with the field, and the current generated in the primary winding is short circuited as

Fig. 104—Pittsfield Type N B Magneto, a True High-Tension Instrument Employing Distinctive Inductor Principle.

Fig. 105—Interrupter of Pittsfield Type N B Magneto.

long as the platinum points are together, but is interrupted upon the points separating, which is accomplished by the interrupter cam coming in contact with the lever. The cam is a two-point member, separating the points twice each complete revolution of the armature shaft to which it is secured and with which it revolves.

The other components of the circuit breaker mechanism are stationary; that is, do not rotate with the armature shaft, but are moved a certain number of degrees to obtain an earlier or later break of the points, or advance and retard of the spark. The housing is provided with two levers for connection to the linkage to facilitate installation of the instrument.

Secondary Circuit.

The beginning of the secondary winding is connected to one end of the primary. The other end of the secondary is attached to a terminal to which is secured a metal plate or bridge in connection with which is the safety spark gap. The high-tension current is conducted from this bridge to the distributing brush by two conductors which are insulated from the metal parts of the instrument. Connections between these conductors is by a carbon brush having a spring.

Distribution of Current.

The distributor plate is of conventional design and with the N B instrument is provided with four segments, these being connected in turn by cable to the spark plugs of the cylinders of the motor. The dis-

tributor brush is of the wipe contact design, and the distributor gear is in mesh with a half-time gear on the armature shaft and rotates in an opposite direction.

The magneto is driven at crankshaft speed with four-cycle, four-cylinder motors, and, as is the case with true high-tension instruments, the primary current is diverted from the secondary windings when it is desired to stop the operation of the motor. Referring again to Fig. 105, it will be noted that the horizontal bar above the circuit breaker carries a terminal. This is wired to the switch, thence to ground. Closing the line short circuits the instrument.

Timing Feature.

It is stated by the maker that the magneto permits of a variation of 45 degrees in timing with a four-cylinder, four-cycle engine, and that the retarded spark is just as efficient as when the lever is advanced. It is also claimed that the engine may be started on a quarter-turn of the crank with the spark lever fully retarded.

The interrupter mechanism is located between the coil and the bearing plate of the inductor and is easily removable by displacing the transformer. The opening of the contact points should be .015625 inch when fully separated, and adjustment is made by loosening a locking nut and turning the movable screw, designated as platinum screw in the drawing at Fig. 106, which shows the components of the instrument.

Timing the Magneto.

The instrument is timed by placing the first cylinder on dead centre or at the completion of the compression stroke. The distributor cap is then removed by pulling outward on a knurled knob and lifting a brass yoke. These parts are shown at Fig. 104, which depicts a front view of the N B instrument, which is also the driving end. The armature shaft is then rotated until the centre of the brush holder of the distributor arm is directly under the line marked on the distributor plate of the lower right hand segment

Fig. 106—Pittsfield Type N B Magneto: At Left, Interrupter Mechanism; Centre, Longitudinal Sectional View with Components Lettered; at Right, Lateral Cross Section Showing Four Pole Shoes.

when facing the driving end of the magneto. The cables to the plugs are connected according to the firing order of the cylinders.

Varying Time of Spark.

The Pittsfield provides variable ignition; that is, the break of the contact points and time of spark may be altered by changing the position of the field poles by means of the sleeve, which is provided with a lever with which the sleeve and the interrupter can be retarded or advanced. The sleeve referred to consists of four pole pieces of magnetic material mounted between ends of non-magnetic metal, and, when oscillated, serves to distort the magnetic flux, and at the same time, causes the contact points to separate sooner or later in relation to the engine piston travel and thus vary the time of sparking in the cylinder.

Pittsfield Dual System.

While the N B type of instrument may be employed for single ignition it can also be utilized as a dual, either with the same set of plugs, or with a separate battery timer and coil with a distinct set of plugs,

Fig. 107—Wiring Plan of Pittsfield Dual System, Including Push Button Type of Switch for Starting from the Seat.

for starting or for regular use. These features are obtained by the use of a separate transformer, whereas the conventional type of true high-tension magnetos employs two windings on the armature, the latter forming a part of the magnetic circuit of the permanent magnets. One end of the primary is usually grounded inside of the armature and the other end is brought out and connected to the interrupter.

In the Pittsfield dual system magneto both the primary and secondary windings are located in a housing at the rear of the instrument. One end of the primary is connected to the interrupter and the other to a three-point switch, so that when the lever is on the magneto side, the magneto operates as a true high-tension instrument. When the switch lever is moved to the battery position, the primary lead is connected to the proper pole of the battery, and the current from the cells is connected in series with the generated current, assisting it or building it up when the engine is operating at slow speeds.

As the resistance of the magneto coil is very small, not more than two dry cells must be employed in a circuit, and according to the wiring diagram

shown at Fig. 107. The various parts should be easily distinguished. In starting with the type of switch shown in the drawing the lever is placed on the battery side and the push button tapped quickly.

The Pittsfield engine starting device is shown at Fig. 108 and was designed especially for service with the Pittsfield instruments for starting the motor from the seat. It is located on the dash and requires but three low-tension wires, these running from the starter to the magneto and engine connections. By placing the key in the proper position and pressing the small button shown in the centre of the face plate, a vibrating current is passed through the starter, resulting in a shower of sparks in the cylinder.

Care and Lubrication.

The ball bearings of the magneto require a few drops of oil monthly, depending upon service, and the places are marked "oil". The gaps of the spark plugs should be between .015625 and .01325 inch. To adjust the interrupter the coil is removed by unscrewing the connecting studs on its top. The type N B Pittsfield is constructed to be driven both clockwise and anti-clockwise, but is not reversible.

The type N A magneto is designed for two-cycle motors, and for a four-cylinder engine is driven at crankshaft speed. It can also be utilized on a four-cycle motor by driving it at camshaft speed. It differs from the type N B in that a four-point cam is employed instead of a two, a different ratio of gearing being utilized, and a jump spark type of distributor is used instead of the regular brush design. The type F shown at Fig. 109 is used on motors of low compression and which require no timing. It is similar to the type N B with the exception that it requires no sleeve for shifting the magnetic poles when advancing and retarding the spark. The interrupter is fastened to the end of the field and is in a fixed position. A jump spark distributor is utilized and is driven at the same ratio as the type N B. The N C magneto is designed for six-cylinder motors.

Fig. 108—Pittsfield Engine Starter.

Fig. 109—Type N F Pittsfield Magneto.

HINTS FOR PROPER MAINTENANCE.

IN REBABBITTING bearings it is essential that the surfaces be clean in order that the anti-friction metal will adhere to the caps. With a good grade of

Easily Constructed Mold for Pouring Bearings, a Tube and Hacksaw Blades Forming the Core.

babbitt and a practical apparatus for holding the bearings to be remetalled, the work may be accomplished satisfactorily. The following method is suggested by a repairman who states that the mold for pouring is constructed easily. The apparatus is shown in an accompanying illustration, and it will be noted that a tube and portions of hacksaw blades are used for the core. The most essential feature is the use of a .375-inch diameter Whitworth hole. This should be tapped through the centre of a small face plate to accommodate a clamping bolt.

A piece of asbestos, the overall size of which should be larger than the two halves of the bearing caps when placed together, is utilized, and a hole drilled in its centre, slightly larger than that of the plate. The core is provided by iron piping of the various diameters and according to the size of bearings to be rebabbitted. The retaining bolt for the bearings is made from a piece of rectangular mild steel, having a .375-inch hole drilled through, and this placed across the top edge of the bearings serves as a clamp. Before tightening the brasses down, two pieces of hacksaw blades are placed between the two halves, so as to separate the metal during the pouring.

Previous to placing the tube in position it should be well coated with lamp black to prevent the metal sticking. The caps should be heated previous to the pouring and should be clean. It is stated that the work results in a casting free from flaws.

REMAGNETIZING MAGNETS.

The remagnetizing of magneto magnets is generally left to the maker of the instrument, and that is, perhaps, the best plan, as the manufacturer has special equipment for the work. However, a method of remagnetizing is given in the Commercial Motor, and the repairman contributing the suggestion was awarded first prize by that publication. The apparatus and wiring diagram are shown in an accompanying illus-

tration, and it will be noted that two storage batteries are utilized, also two bulbs.

To make the apparatus two pieces of soft iron are employed, about six inches long and about 1.25 inches in diameter. These are used for the cores. The base is constructed of a piece of mild steel plate in which are tapped two .5-inch holes and these are threaded to take one end of the iron core.

Before screwing the core pieces in position, they are wound with an equal number of turns of No. 22 gauge insulated copper wire, the ends being left free. To these are attached four terminals. The wires are connected up to a pair of storage batteries as shown, and the latter are so wired that the polarity of the soft iron cores, indicated by the compass needle, is north and south respectively.

The inventor of the apparatus states that should the coils show signs of overheating, one or more lamps should be placed in each circuit to introduce resistance. Before beginning the work it is essential to ascertain the polarity, and this is accomplished by the aid of a compass needle. The magneto magnets must next be marked north and south, respectively, before there is any opportunity of reversing the process by confusing the poles.

To use the apparatus it is stated that it is only necessary to place the magnets with their opposite poles in contact with the cores, until they have absorbed sufficient magnetism to enable them to sustain a weight of 10 pounds, after which they are ready to be replaced on the magneto. In the drawing the magnet to be treated is the inner member.

STARTING SEIZED PISTONS.

The following suggestion is made for starting seized pistons: Place about a pint of kerosene in each cylinder, then jack up one of the front wheels so that it clears the ground by at least two inches. Next place a jack under the starting handle with the clutch section engaging with the crankshaft. Lower the jack until the handle carries the weight of the machine. It

Remagnetizing Magneto Magnets by Apparatus Designed by a Repairman.

is stated by the repairman suggesting the plan that by this method the most obstinate piston may be started.

STEWART AUTOMATIC CARBURETOR ADJUSTER.

THE Stewart-Warner Speedometer Corporation, Chicago, is introducing a thermo-automatic carburetor adjuster which is designed to automatically

Fig. 1—Chart Showing Various Carburetor Adjustments, That at E Indicating Where It is Stated the Stewart Provides the Richest Mixture Possible.

regulate the operation of the carburetor by temperature. The device is so constructed that it may be utilized with varying makes of carburetors and to regulate the amount of air admitted or the fuel supply. This is performed automatically, the augmenting or decreasing of the air and fuel being performed by a novel application of the use of mercury, a metal which responds readily and accurately to changes in temperature. In the Stewart device the expansion and contraction of mercury adjust the carburetor.

It is well known that a rich mixture makes for easy starting of a cold motor, and that the average driver adjusts the carburetor so as to enrich the mixture at low motor speeds. At higher ratios, and when the cylinders have attained an operating temperature of, say, from 170 to 180 degrees Fahrenheit, the flow of fuel or its emergence from the jet is considerably faster than at starting. Prof. Brewer, an English authority on carburetion, holds that there is a difference of 39 per cent. from the same sized opening in a change of 15 degrees.

A rich mixture for starting has its advantages, but as previously pointed out, upon the engine becoming warm, there is apt to be too great a supply of fuel in proportion to the air at high speeds. This makes for waste of fuel, to say nothing of creating sooty deposits on the cylinder walls, valves, etc. While the modern carburetor manufacturer makes provision for

Fig. 2—Stewart Thermo-Adjuster, Which Automatically Regulates the Air or Fuel by a Novel Use of Mercury.

enriching the mixture for starting, providing dash or steering column adjustment of the air, the judgment employed by the driver is not always the best.

The inventor of the Stewart thermo-automatic adjuster states that it increases the density of the mixture for starting when the cylinders are cold; automatically proportions the fuel or air in accordance with the temperature of the combustion, preventing waste of fuel, and obtains a perfect mixture throughout the entire range of adjustment on any carburetor.

The Stewart thermo-automatic carburetor adjuster is composed of a metal bulb, connection tubing and a Bardon coil enclosed in a metal box, from which protrudes a plunger or pushrod as shown at Fig. 2. The bulb is tapped into the water circulation system, in the outlet water manifold, for example, as shown at Fig. 3, and the adjuster proper is attached to the carburetor in such manner as to permit the pushrod or plunger to actuate the air valve or needle valve of the carburetor. The movements of this rod are indicated by the dotted lines at Fig. 2.

The temperature of the fluid in which the bulb is immersed causes the mercury to contract or expand,

Fig. 3—Showing the Stewart Device Installed on a Rayfield Carburetor—The Bulb Is Located in the Outlet Water Manifold.

as the case may be, and the pushrod is actuated accordingly. It is claimed by the inventor that the thermostat will operate within one degree of the indicated temperature, and that the maximum valve movement is .3125 inch.

With the Stewart, the carburetor is adjusted as nearly correct as possible, but the adjustment of the device is so made as to have no effect except when the temperature of the water jacket falls below 180 degrees Fahrenheit. At this point, and to 40 degrees, it is held that the Stewart will automatically regulate the mixture.

The chart at Fig. 1 brings out the points emphasized in the Stewart device. AB represents the entire range of adjustment on any carburetor, A being the point where back firing occurs. C indicates the 180-degree point, held to be the most efficient and economical. D is the 90-degree point, where it is claimed that the majority of carburetors are adjusted so as to obtain easy starting. E is the 40-degree point, where it is stated the Stewart device provides the richest mixture possible.

The intersecting line C denotes the ideal adjustment, where the most economical and most efficient proportions of fuel and air are obtained when the motor is operating under perfect conditions and the temperature of the water is 180 degrees. With the lowering of the temperature the conditions represented by A will be experienced. With the adjustment as indicated by D the easy starting is offset by too rich a mixture, upon the cylinders attaining their working temperature. E indicates the 40-degree point, where it is pointed out that the Stewart device provides a rich mixture; that is, under conditions requiring more fuel or less air, as in starting in low temperatures.

With the Rayfield carburetor, as shown at Fig. 3, the Stewart operates on the air valve, a loose sliding collar being employed. At low temperatures the push-rod increases the tension of the spring controlling the air valve, decreasing the supply of air and enriching the mixture to meet conditions. Under ideal operating conditions the Stewart is inactive. Changes in temperature, however, are automatically compensated for as previously explained.

The Stewart thermo-automatic adjuster is designed for service with all types of carburetors and eliminates changing the proportions of fuel and air. It is the intention of the company to manufacture the Stewart adjuster for application to the exterior of the circulating system, eliminating the tapping of the water pipes or manifolds.

SCHOOL FOR GARFORD DRIVERS.

With keen realization of the advantages obtaining from the services of experienced well trained men driving vehicles, the Overland-Garford Sales Company, Cleveland, O., has established a school in that city for the benefit of men who are now engaged as drivers or desire to have employment as such. The company is agent for Garford trucks and Willys Utility and Overland wagons, and having demand for the services of capable drivers, familiar with the machines named, which it was not always able to supply, for the protection of its own and its customers' interests the company organized a school.

The school has been well attended and can be considered as a success from every point of view. The course covers a period of six weeks and during that time each student receives 12 lessons and three competent men instruct the classes, following theory by practical work on machines of the types stated.

"SAFETY FIRST" EDUCATION.

The people of Indianapolis, Ind., are now experiencing a "safety first" campaign, which was inaugurated by the Hoosier Motor Club of that city, and which will be continued as long as may be necessary to minimize accidents in the streets. The club is distributing to the school children printed advice of how to avoid danger in the streets, and a series of advertisements

will be printed which will ask all persons, especially drivers of vehicles of any kind, to observe traffic and other regulations. The police will also be instructed, if the desires of the club are observed by the mayor, to strictly enforce all laws regarding street traffic, the purpose being to make the streets as safe as is practical for both vehicle users and pedestrians.

MAY TAX MOTOR TRUCK SALESMEN.

A bill is now pending in the Kentucky legislature that contains a provision that all salesmen for automobile vehicles in counties containing cities of the first and second classes shall pay annual license fees of \$100, in counties containing cities of the third and fourth classes license fees of \$50, and in all other counties license fees of \$30 each, and that the revenue shall be made a fund for the improvement of the highways, each county to receive the amount of the license fees collected within that county from the fund. It is needless to state that the bill is being very vigorously opposed by those who are in any way interested in motor vehicle distribution.

CONNECTICUT INCREASES FEES.

Under an opinion of Attorney General John I. Light of Connecticut, owners of passenger vehicles that have converted them to delivery use will be required to pay the registration tax for passenger cars, which is 50 cents a horsepower. This will mean a considerable increase in the fees to be paid. Until now the machines have been registered in the commercial class on which the registration fee is \$7 for any vehicle of 1400 pounds capacity or less, and \$3 for each additional 1000 pounds. By this ruling a man who formerly paid \$7 for a converted 40 horsepower car will now have to contribute \$20 to satisfy the state authorities.

The Goodyear Tire & Rubber Company has appointed E. P. Dowse of Grand Rapids, Mich., manager of its Toledo, O., branch, vice M. M. Norton, who has been named district manager for the company, and F. H. Casebeer, manager at Oklahoma City, Okla., has been transferred to the managership of the St. Louis, Mo., branch, he being succeeded by F. J. Arling of the St. Louis branch.

The entire sale of Cleveland trucks is directed by C. D. Paxson, Cleveland, O., the machines being shipped by the maker, the Lewis Spring & Axle Company, Jackson, Mich., according to orders from the agents and representatives.

A factory at Tacoma, Wash., is projected by the Gramm-Bernstein Company, Lima, O., maker of B. A. Gramm's trucks, and if the plans are carried out this will probably be built the coming spring.

CORRESPONDENCE WITH THE READER.

Filtering Lubricants.

(56)—Some time ago you published an illustration showing a plan whereby old lubricant could be filtered and used over again. The story appeared in your magazine, but I fail to find it as one or two copies are missing. Would it be asking too much to republish the sketch of the filter?

OLD SUBSCRIBER.

Waterbury, Conn., Jan. 23.

The article referred to was published in the August, 1913, issue of the MOTOR TRUCK. The

Fig. 1—Multiple Disc Clutch Disassembled to Make Clear the Operation of Parts and Method of Adjustment.

sketch of the filter is shown at Fig. 2, and consists of a round tank, a fine mesh brass screen, an extra vessel, two ordinary tin funnels, some metal tubing and a petcock. A five-gallon can is to be preferred. Remove its top and solder three projections to the walls as shown to support each funnel and the screen. Drill a hole in the lower side of the container and fit .25-inch copper tubing, which is led to an extra vessel. The installation of a petcock in the line is advisable, as it will permit of shutting off the dripping oil when the filter is to be cleaned. As the drawing is lettered it should be a simple matter to construct and operate the filter.

Multiple Disc Clutch.

(57)—The firm with which I am employed uses a K-R-I-T car which has a disc clutch. It is not working right, as it slips. What is the proper method of adjusting it, etc.?

DRIVER.

Kansas City, Mo., Jan. 17.

The clutch mentioned is composed of 10 large steel discs and 11 smaller plates, as shown at Fig. 1. While it would appear that the large discs are similar, four are left hand and six are right hand. The reason for this is obvious. By placing one disc on top of the other it will be noted that the small springs cut in the edge of the disc do not bear together, and that the 11 small discs C are interleaved between each of the 10 large plates. The latter fit onto three pins securely fastened to the flywheel and the small discs are secured to the clutch drum or body A, which revolves freely on the end of the crankshaft, and to which the gear K is fitted.

The discs are held in place on the drum by the three adjustable eye bolts D. To these are secured the toggles E E, one end of which bears against the disc plate F, the other end of the toggle bearing against the cone G, in the bore of which is located a strong spring H. The action of this spring against the cone, toggles, etc., is to keep the large and small

discs together. The clutch pedal is connected to the clutch by means of a shaft and two pawls which fit into a groove I, and when the pedal is pushed forward or depressed its motion pulls the cone G back, thereby releasing the pressure from the 11 small discs, permitting the flywheel to revolve the large plates without rotating the smaller ones and subsequently revolve the gear K. These parts are shown at Fig. 1.

To adjust the clutch the pedal is fully depressed, which will bring the cone G towards the bearing J. To hold the clutch out place a stick against the pedal or place some object between the cone G and the hub of clutch D at X. Remove the pin passing through the eyebolt D and make one turn to the right. Replace toggle pin and adjust the next toggle in the same manner; also the third.

The discs operate in oil and should the clutch slip it should be flushed with kerosene. Depress and release the clutch several times and crank the motor to allow the oil to work between the plates. Remove all kerosene and refill with fresh lubricant.

The business of S. F. Bowser & Co., Fort Wayne, Ind., manufacturer of gasoline storage equipment for garages, was stated by the general manager at the annual convention of the Pacemakers' Club, composed of salesmen for that concern, to have reached the \$4,000,000 mark last year, this being practically the same as for 1912. In other words, the business of the company showed no decrease.

G. O. Bristol, formerly connected with the Chicago branch, has been named manager of the commercial vehicle sale department of the Motz Tire & Rubber Company of Akron, O., and is now located in Akron.

Fig. 2—Oil Filter for Renovating Old Lubricants.

GARAGE AND SERVICE STATION EQUIPMENT.

THE Hauck Manufacturing Company, 140 Livingston street, Brooklyn, N. Y., is marketing the Hauck patent kerosene torch, which is designed for

Hauck Kerosene Torch in Service with Furnace Made by the Same Concern.

general shop work and is held to be more efficient and economical than a gasoline unit. The maker states that the cost of operation is very low; that considerably more heat is obtained with kerosene than gasoline, and that the fuel is not only cheaper, but it is readily obtained. Another advantage in kerosene is held to be that it may be stored without restriction and is safer to use than gasoline.

The company states that its No. 14 torch will melt a piece of copper .5 by .25 inch, in three minutes, or a one-inch brass rod in two minutes. It is utilized in conjunction with a heating furnace, as shown in the accompanying illustration, providing a combination especially adapted for tool dressing, tempering, annealing and other heating operations. The furnace is 10 inches long, 10 wide and six high; made of cast iron and lined with a high grade fire brick. The company states its torches have been adopted by the United States government.

ATLAS BALL GAUGE.

The Atlas Ball Company, Philadelphia, is placing on the market a new ball gauge which can be utilized as a limit gauge, the ball on one end being gauged to 1.251 inches, and the other 1.249 inches. Complete details are supplied by the company, which is located at 201 Glenwood avenue.

SPARTON HAMMER.

The Drop Forging Company, Jersey City, N. J., is manufacturing the Sparton hammer, shown in an accompanying illustration, and the maker calls attention to the design, stating that it is particularly adapt-

Sparton Hammer, Combining Screw Driver, Tire Iron, Etc.

ed to motor car work where a hammer, screw driver and tire iron are constantly required. It is also claimed that it has the essential qualities of a general utility tool.

MINIMAX PUMPING OUTFIT.

Herz & Co., New York City, is marketing a portable type of electric air compressor, termed the Minimax garage pumping outfit. It is a complete air compressor equipment mounted on a truck having a convenient handle for moving the unit as desired. A feature of the truck is the use of a metal tray which is sufficiently large to accommodate tools in addition to the motor, pump and tank.

The air compressor is a double-cylinder pump with cranks set at 180 degrees. The cylinders have a bore of 1.375 inches and stroke of 2.5, and the operating

Minimax Garage Pumping Outfit Marketed by Herz & Co.

speed is 400 revolutions a minute. The height is 11 inches, width 3.5. The electric motor is rated at .25 horsepower, and is supplied for direct or alternating current and different voltages. The gears driving the pump are accurately cut, of high grade material, and are enclosed by a guard.

The tank is of cast iron, and all air passing to it flows through a check valve of special design. The tank is 20 inches long and nine inside diameter. The capacity of the tank is equivalent to 5.5 gallons of water. It is tested to a safety pressure of 250 pounds. A safety valve is placed behind the manometer and may be set to a pressure up to 125 pounds, and the valve is stated to be very accurate in its action and will not require attention.

One of the qualities of the equipment is that all wires between the motor and the switch are carefully protected against damage or leakage of current. Connection to the supply of electricity is by a cord and a lamp socket. The equipment includes a starting switch and suitable length of steel covered hose.

EASTERN GASOLINE FUNNEL FILTER.

The Eastern Oil Tank Company, 146 Fletcher street, Lowell, Mass., is manufacturing the Eastern gasoline funnel filter, a part sectional view of which is

Eastern Gasoline Funnel Filter for Separating Water and Other Foreign Elements from the Fuel.

shown herewith, also the construction of the inside strainer. The maker states that the design is very efficient in separating water and other foreign elements from the fuel and that the construction permits of easy disassembly and replacement.

As will be noted by the illustration the gasoline is filtered through a mesh and an inside strainer is included, the latter catching all water. The maker states that the funnel can be used in rainy weather without any water reaching the tank and that splashing of fuel is prevented. The funnel filter is made to be carried easily in the car, assuring the use of clean fuel when purchased on the road, etc.

STARR OVAL CUTTER.

Cutting circular gaskets, etc., is a simple matter compared to oval members, and generally considerable time is required with the latter in order to obtain perfect work. The Shawver Company, Springfield, O., is marketing a practical device, for cutting ovals, termed the Starr-Springfield cutter, which is shown herewith. The No. 1 tool will cut any size circle up to 15 inches, and ovals up to 15 by 22 inches. The No. 2 cuts circles up to 22 inches and ovals to 22 by 34 inches.

The bars are graduated by inches and fractions of fourths, permitting the operator to set the machine instantly to cut the size of opening previously determined. The machine is equipped with an automatic stop, limiting the downward movement of the knife, making it impossible to cut into the table top. The four corners have adjustments for raising or lowering, so that the machine may be levelled to conform to the table surface.

A quick acting clamp is provided for holding any thickness mat board up to .25 inch, and is quickly adjusted to any size opening. When the machine is not

at work the clamp and its components rise from the table, a feature the maker states is not found in any other oval cutter. The complete equipment includes a cutting board, one wheel glass cutter, one embossing wheel, one knife for cutting 23-degree bevel edge, one knife for cutting a square edge, one stub knife for cutting long, narrow ovals, and a wrench.

VULCAN CHAIN PIPE VISE.

J. H. Williams & Co., 150 Hamilton avenue, Brooklyn, N. Y., is manufacturing the Vulcan chain pipe vise, which is constructed of bright steel throughout and is claimed to be unbreakable. It is also compact in design and may be set up readily for service. It has drop forged steel jaws, tempered for file sharpening. The vise is made in three sizes with pipe capacities of from .125 to eight inches.

ERICKSON HOSE CLAMP.

P. E. Erickson & Son, Port Chester, N. Y., is manufacturing a new type of hose clamp. On end of the band intersects the other and this with a screw adjustment permits of use with different diameter hose. The standard finish is electro-galvanized, but other finishes are provided. The sizes range from .375 to two inches.

WANTS SUBSTITUTE FOR RUBBER.

A prize equal to \$10,000 has been offered by the minister of war of Austria for a material or a device that will be the equal of rubber when utilized as a motor truck tire or incorporated with the wheels of machines. The conditions are that the material shall have elasticity and requisite adhesion and be more enduring than is rubber, or if no more than equal to rubber in its qualities the original cost must be smaller; that the weight must be no more than rubber when formed as a tire. Those who shall enter competition for the prize must submit to the Automobil-Versuchsabteilung, VI Gumpendorferstrasse, I, Vienna, Austria, a model in standard or reduced size or on

Starr-Springfield Oval Cutter, Which Will Also Cut Circles up to 15 inches.

before June 30, 1914. Information in detail form relative to the competition can be obtained by application to K. K. Kreigsministerium, Vienna, Austria.

New Commercial Car Accessories

Master Spark Plug.

The Hartford Machine Screw Company, Hartford, Conn., is manufacturing what is termed the Master plug.

which is marketed at a moderate price because of a production in quantity and improved manufacturing facilities. The porcelain is made extra heavy and the company states that the design will withstand strains which break down ordinary insulators.

The seat for the porcelain is very wide and well cushioned, and ample margin is provided for the effects of expansion and contraction. One of the qualities emphasized in the Master plug is that it may be easily and quickly disassembled and the parts replaced without interfering with their efficiency. Throughout the best of workmanship and material is incorporated. The Master is made in standard threads and with varying lengths of base to meet the requirements of varying motor design. The company is licensed under the Canadian patent.

J-M Mobilite Signal Lamp.

The H. W. Johns-Manville Company, New York City, is marketing a practical compact signalling device, which is utilized to warn approaching vehicles of the direction to be taken by the machine, and provision is also made for notifying the other car when a stop is to be made. The new light is known as the J-M Mobilite signal lamp, and consists of three small electric lamps mounted on an aluminum base finished in ebony black. When the steering wheel is turned to the right or left, a white arrow automatically appears in the corresponding lamp, indicating the direction the car will proceed. When the clutch is thrown out, the word "Stop" appears in red letters in the centre dial of the device.

The signals are operated by self-

contained, water proof contact devices attached to the steering gear and the clutch. Each unit comprises a vulcanized rubber socket fitted with a special tungsten bulb and a powerful reflector. The lamps consume but little current, and can be operated economically on dry cells. An illustrated booklet on the lamps will be mailed free on request.

Empire Fuel Economizer.

The Brown-Taylor-Greene Company, Chicago, is manufacturing the Empire gasoline economizer, which differs from the conventional types of devices marketed for this purpose in that the control of auxiliary air admitted is automatically, not manually, operated and in proportion to the speed of the motor. This feature is obtained by the connection of the economizer to the throttle linkage.

The device is very compact and well designed. The control of the auxiliary air admitted to the intake manifold is by suitably proportioned

ports, which are uncovered by a piston or plunger member, the last named being actuated by the movement of the throttle. It is held that the Empire supplies the required amount of air at all speeds. Claims of 20 to 80 per cent. in fuel economy are made.

Rexo II Electric Horn.

The Dean Electric Company, Elyria, O., which concern has marketed a number of electric signalling devices, has augmented its line with a new design termed the Rexo II. One

of the features of the horn is that its retail price is less than \$4. This does not mean that quality or workmanship has been sacrificed, as the company is employing the best of material and the details of construction are as carefully executed as in its higher priced horns. The extreme low price is explained by the statement that the Dean Electric Company plans a production of 100,000 during the coming season.

Several finishes are offered, these comprising the usual black and nickel, or black and brass. Two coats of enamel are applied to each horn and each is baked on, a special process being employed. The company states that the finish is weather and heat proof and that it will not chip.

Arnold Electric Plugs.

The H. W. Johns-Manville Company, Madison avenue and 41st street, New York City, is now marketing the

Arnold electric heating plugs, which are held to solve the starting problem when the motor is exposed to low temperatures. The complete equipment comprises two electric plugs and a resistance coil, the latter being inserted in the intake manifold. The location of the plugs is shown in the accompanying illustration.

By passing a current through the coil member a high degree of heat is obtained, resulting in raising the temperature of the mixture to a point making for instantaneous and complete combustion. The heat not only makes for a complete blending of the fuel and air, but any particles of gasoline not carbureted by the carburetor are converted into useful mixture by the heat. It is this that provides the easy starting feature emphasized by the Arnold electric plugs.

The terminals of the plugs are connected to a six-volt storage battery.

Rex Shock Absorbers.

The Rex Shock Absorber Company, New Rochelle, N. Y., and Stamford, Conn., is manufacturing the Rex shock absorbers, which are designed for use on front and rear springs and for varying suspensions. A feature emphasized by the maker is the use of a double volute spring in such manner that it absorbs the upward and downward movements and with the use of but one adjusting nut.

The frame of the shackle is made in one piece and the inner fork is similarly constructed. The last named has a compact guide inside the outer frame, an arrangement that the maker states makes for great strength, as well as eliminates wear of the mechanism. The absorber spring is retained in a grease and oil tight cover, and is accessible.

BOSTON TRUCK SHOW A NATIONAL EVENT.

THE show of motor service wagons and trucks at Mechanics' building, Boston, beginning the evening of March 17 and continuing to March 21, organized by the Boston Commercial Motor Vehicle Association, will be the third exclusive exhibition of machines of the types named held in that city. Because the manufacturers decided to abandon shows of service vehicles in New York and Chicago, after two years' experience, the supposition may be that the Boston exposition will be practically a local display, but as a matter of fact the show will be national in character from every point of view.

The Boston association, before the conclusion of its second annual show, decided to organize that which will be held next month, and the preparations have been making for practically a year. The exhibition will be directed by Chester I. Campbell, who has a more intimate knowledge of the market than any other man in New England, because of his constant association with the industry and trade, and he has sought to make the show more comprehensive, and its influence greater, than ever before.

The conditions in Boston are different than in any other locality. The shows have always attracted visitors from all sections of New England and the British provinces, and the results at previous exhibitions have proven that the visitors are buyers, attracted because of their interest in the economic value of motor vehicles and the possibilities for examining and comparing types of machines that will meet requirements.

Boston is a purchasing centre. It attracts business men at all times, for it is accessible from every part of New England in a few hours. The show is held at a time when business men in large numbers visit Boston. The end of winter means that the greatest period of activity for haulage is close at hand, and transportation needs are not only pressing, but must be supplied. Instead of a period of winter inactivity and uncertainty as to demands of business later on, those having need of haulage equipment must be prepared, and decisions must be reached.

The Boston shows have always been largely productive, not from the viewpoint of making agencies or securing representatives for selling organizations, but through the sales made to those who want machines and want what will best serve their purposes. This has been true especially of the motor truck exhibitions, for much time is given over to systematic examination of exhibits by those representing large interests, relying upon the reports made by engineers. The New England business man is inclined to regard expert advice with extreme favor, and this means that personal interest or sentiment is incidental when investigations are made as to qualities.

The preparations for the truck show are practically completed. The space in Grand and Exhibition halls was long since disposed of, and practically all of the

basement has been allotted. The hall floors will be devoted largely to the representative makes of machines, for some of the exhibitors made application previous to the show of 1913 for the spaces they will show in, and this fact has transformed the basement into what may be termed a department for machines produced within a year.

While the types of vehicles will range from the cyclecar adapted for package distribution to the truck of largest size, the greatest number of machines seen will be of capacities from 1500 to 5000 pounds, with the majority of these of smaller sizes. This would appear to indicate that the industry has developed many types that can be adapted to a diversity of requirements to serve the purposes of concerns that require quick haulage of light loads, but one man being required to operate them.

Units of this design can be added to equipment to provide for a reasonable increase of business at moderate expense. The cost of operation is relatively small, and the elasticity of service and the reserve capacity is very large. Many exhibitors will feature machines of this kind, and because of the wide range of design, construction and price there is no question that a large number of visitors will be interested.

Another feature will be the progress made in body designing, for a chief thought with every vehicle builder is to furnish bodies that will meet with a general demand, while special constructions to serve individual requirements will be of much interest to those requiring equipment of unusual design.

Many trucks of even two tons capacity are now fitted with quick discharging bodies, and the development of body hoists will be a fruitful subject for study by those who have need for vehicles so fitted. There are numerous new adaptations of power, protective devices, and means of control for body hoisting apparatus, and the exhibits of these will be numerous.

Each machine will have its own characteristics of design that may have special interest, but what will be weighed with much care will be the governing devices, the protection of mechanism, the provision for lubricating moving parts, means for adjustment to compensate for wear, insurance against stresses, and other refinement details. Those purchasing machines realize that endurance is the one factor that cannot be determined, other than by design that will insure sufficient margin of strength, and proportioning of parts, so that these will not only wear slowly, but in the event of renewals, the assemblies need not be materially changed.

The show will attract the attention of the industry, because this will be the only real opportunity of the year for the engineering forces to study the machines and estimate the progressions made by the designers, and from this aspect will be a considerable influence for the advancement that shall be made in future.

FEDERAL TRUCKS FOR WAR.**Portugal Purchasing Motor Equipment for Service with Republic's Army.**

Whether or not the name Federal, which suggests a democracy and a republican form of government, was a factor in the determination of the war department of Portugal to provide Federal machines when it began to motorize the equipment of its army, the fact remains that the vehicles produced by the Federal Motor Truck Company, Detroit, were purchased.

Since the inauguration of the republic, Portugal has been under the administration of an element that was antagonistic to royalty, and there has been no sentiment prevailing that was subservient to custom, prestige or practise, and when the war department investigated the machines that would be suited to its purposes the vehicles made by European and American builders were considered impartially.

There is no question that high class trucks and wagons are built in Europe, and the war department made inquiry into the qualities of all that were regarded as being suited to its purposes. As a result of this investigation the first machine was ordered March 3, 1913, the intention being to experiment with this and to determine from its work whether or not others would be required. The machine was delivered promptly and when this had been worked for about five months decision was made to purchase four more, the order being given Sept. 25.

Before the delivery of this order, on Oct. 6, the third order for four Federals was received, and directly following the receipt the fourth order, this time for four, was sent in. With 13 trucks available the war department sent the fifth order, this time for four, which was cabled Jan. 3, and this shipment was dispatched promptly. The details of the uses made of the trucks are not known, but there is belief that they are in general transportation service for the army, although not as yet used for field purposes.

At Victoria, B. C., a company has been organized to operate a line of motor omnibuses that has capital of \$50,000, and the organizers will compete with the street railroad, which recently increased fares. The shares in the company are valued at \$1 and any person desiring can become a stockholder. The fares proposed for the omnibus line range from two to five cents.

A factory to build undertakers' motor wagons is to be established by the Keystone Vehicle Company, Columbus, O., a concern recently formed in that city with capital of \$15,000.

A dividend of 1.75 per cent. on preferred stock, payable April 1, has been declared by the B. F. Goodrich Company, Akron, O.

WILL STUDY MACY DELIVERY.**New York City Department Store Service to be Considered by Research Corps.**

The delivery service of the store of R. H. Macy & Co., New York City, is to be studied and reported on by the research department of the electrical engineering school of the Massachusetts Institute of Technology, under the direction of Instructor Harry F. Thomson, who will have the assistance of several students in the work. This will be the first instance in which a large store, or any concern, in fact, has availed itself of the practical possibilities of such work. Two years ago the institute was interested in transportation research by the Edison Electric Illuminating Company of Boston, which placed a fund at the disposal of the department, and since that time the work has been carried on, being supervised by Prof. Harold Pender.

The study of the subject up to the present time has been with a view of obtaining sufficient accurate data to justify conclusions and to determine facts with reference especially to operating cost of different types of vehicles in varying works and in variable conditions. Several reports have been published that have material value. The institute has the co-operation of a considerable number of concerns in different sections of the country, and has through systematic study and observation accumulated a valuable fund of information.

With knowledge of the work that has been accomplished the Macy company asks that an investigation be made of its delivery service, which is done by its own organization as far east as Stamford, Conn., as far north as Ossining, N. Y., as far south as Seabright, N. J., and as far west as Plainfield, N. J. The work is done by transfer from the store and warehouses to distributing stations, gasoline and electric trucks and wagons and horse trucks and wagons being utilized. In all about 400 vehicles are used and the expense of distribution is placed at close to \$1,000,000. The investigation will be continued for whatever period is necessary, and the expectation is that the result will be a report that will make recommendation of probable economies.

The Wright Storage Battery Company has succeeded the A. Bologensic Company of Poughkeepsie, N. Y., and with capital of \$100,000 will manufacture batteries with A. M. Sherer, formerly with the Electric Storage Battery Company, Philadelphia, as superintendent.

The number of exhibitors of motor trucks and wagons at the Newark, N. J., show, which will be opened Feb. 21 and continued for one week, will be extremely large, as practically every New York City dealer who has New Jersey territory will display.

STRENGTH LIMITS OF TRUCK WHEELS.

Definite Data of Extreme Value to Motor Vehicle Industry Obtained by Comparative Tests of Wood and Composite Types in Laboratory of Perdue University.

WHEEL building may be regarded as a detail of vehicle construction, but since the utilization of the motor vehicle some attention has been given to wheel designing, largely from the fact that with pleasure cars lightness and extreme strength have been demanded by those who desire speed, and that those who build trucks and wagons realize that the road stresses under loads are extreme and that liberal margins of safety should be provided.

The spoked wheel is a development from the disc that was first used in crude form and then perfected with use, the metal tire being used to minimize wear and protect the disc. The binding influence of the tire was utilized so far as possible, considering the variation in wood from climatic conditions. The expansion and contraction of wood by the absorption of moisture and drying varies considerably, and this is a factor of considerable importance.

The standard wood wheel of today is a development of the type used for carts and wagons, the diameter being decreased for two reasons, the one to lower the centre of gravity of the load, and the other to minimize tire expense. Every mechanic knows that the larger the wheel the longer the lever arm, and the greater the wheel diameter the easier a vehicle of given weight can be moved on a stated surface. Theoretically, with reference to conservation of power, a large wheel is preferable to one that is small, but there are limitations because of the necessity of building the large wheel sufficiently strong to carry the weight and to endure the stresses, and there must be proportionate increase of structural material to afford this strength.

The Artillery Type Wheel.

The motor truck wheel is generally designated as "artillery type", which means that the design is regarded as similar to that used for wheels for field artillery gun carriages and caissons, and implies to the engineer a heavy construction that is intended to endure the varying conditions of rough road haulage and the extreme shocks from the discharge of the cannon. This design has been more or less modified by the builders of trucks, and one can say that there is little resemblance between the wheels of motor wagons and

those used for military purposes, but the general term has been applied and it has been accepted as meaning practically any modification of wheels as found in motor service vehicles.

In theory the ideal wheel is simple. In practise the construction that will embody every quality and have none of the faults has been vainly sought. That this is so is not strange, for practically every engineering subject studied has led to the establishment of factors that must necessarily be regarded. The period the development of wheels has been attempted is exceedingly brief, and there are those who have sought to improve the wooden wheel, while others have directed their endeavors toward the creation of what would appear to have the desirable qualities. That wheel design is a matter of real importance, and is not a mere

The Master Car Builders' Machine, Perdue University Engineering Laboratory, Used with Attachments Shown for Torsion Tests of Truck Wheels.

detail of vehicle building, is evident from the attention given to development both in this country and abroad.

Metal Wheels Abroad.

That European engineers have more closely investigated metal wheels is not so much from the lack of wood that is suitable for construction as from the fact that study of the subject demonstrated the need of the application of engineering principles, and so far as scientific knowledge is concerned foreign engineers have an undoubted advantage. In this connection it may be well to emphasize that French and English builders developed wire wheels for pleasure cars on scientific principles because of investigation of motor vehicle requirements, while American builders seem-

The Tested Wheels at the Completion of the Torsion Tests: At Left the Two-Ton Wood Wheel, and at Right the 1.5-Ton Indestructible Steel Wheel.

ingly contented themselves with the belief that wire construction as contrasted with wood had comparatively little justification.

When one understands that the wheel building industry has attained considerable proportions, is well established, and that wood has seemingly met all requirements so far as known, a proposed change to metal would not be favored by wheel builders, and engineers who have little or no knowledge of metal construction would not advocate adoption of what was unknown or untried. The wire wheel was developed from bicycle design and construction, and it was first adopted because of its strength and light weight. Its development has never been closely followed, but for several years before such wheels were seriously considered in America they were used to considerable extent abroad.

About the same time that wire wheels were taken up in Europe some attention was given to metal wheels for use, but as these were in every sense experimental, a period of several years passed before sufficient data were known to justify definite statement. But as the development had been made according to engineering principles and under careful observation, the facts obtained were regarded as dependable.

American Engineers Study Problem.

Not until the success of the metal wheel builders of Europe had been made public did American engineers devote themselves to study of wheels, and this was due very generally to the assumption that the wheel manufacturers had kept pace with the demands of the industry. This statement should not be understood as a reflection, but as a reason why metal wheels have been more generally used and better understood abroad than in America. Today the number of steel wheels in service is comparatively few. Several builders of trucks have adopted them, and in three instances at least these are the creations of truck engineers, there being but two concerns making them commercially. These are all of the cast type and the metals are either steel or malleable iron.

Several wheel builders who have adopted scientific methods and engineering principles of manufacturing, have sought to obtain definite data relative to the comparative merits of their productions, and in two instances at least have had wheels tested in laboratory

tests to determine the relative strength of different sizes and designs. One association of wheel manufacturers has also secured information from laboratory trials, but these data have not been made public, the members no doubt regarding themselves as being entitled to it for their personal use.

Up to the present time, however, the facts known relate to wood wheels only, and

the only detail concerning steel wheels resultant from a test by scientific means that is known is that of cast steel wheels produced by the Sheldon Spring & Axle Company, which were tested before a committee representing the Society of Automobile Engineers early in 1913. This concern had developed a wheel that was regarded as being sufficiently perfected to justify its production commercially, and the company arranged the test for the purpose of demonstrating the strength of the material and the quality of the design.

This test was first to determine the strength of the wheel for resisting deflection from shock applied to the rim, and to learn the strength to resist distortion from a constant pressure. In the first instance the application might be likened to the effect of a shock, as when a machine skidded and came in contact with an immovable object, and the other was to determine the quality of the wheel to a finality or destruction. By measuring these forces very accurate determination could be made. The one test was that of a dynamic pendulum, the wheel being immovably fixed and the weight being swung back to specified distances and released, this affording definite measurement of the impact. The other was by the application of a hydraulic jack by which a pressure of 25 tons was brought against the rim of the wheel, this being held in a mammoth clamp, the pressure being so applied that the wheel was resisting it from the hub to the periphery on one side only. The extent of deformation of the wheel subjected to the pendulum test and the weight of the blows gave data for the one test, and the pressure necessary to distort the wheel was the information developed by the other. The condition of the metal following the tests indicated the degree of resistance and whether or not fractures developed. Obviously the tests were much more severe than would be realized in normal service.

Tests of wood wheels have been with a view of developing the resistance to "dishing" strains, and compression strains. In the former the wheel rims were supported at the rim on three or four points and the pressure applied at the hub, on the outside of the wheel, against the initial dish. The compression or loading strain was applied by placing the wheel vertically and applying pressure on the rim between two spokes to such extent that the rim was broken, or di-

rectly upon the rim so that the load was borne by a spoke.

A series of tests with wheels was made recently at the laboratory of the school of engineering connected with Perdue University, Lafayette, Ind., which is of extreme interest to the wheel industry, and to all using motor vehicles, because this was the first comparative trial of wood and composite wheels in America. The results were of decided value to engineers, for these establish data that may be the foundation for wheel engineering. The reason for the test was to determine the comparative value of the Indestructible wheel, which is built by the Indestructible Wheel Company, Lebanon, Ind., under patents owned by A. M. Lofland, the inventor, and manager of the company.

Construction of Indestructible Design.

The principle of the Indestructible wheel is different than anything yet created, and the construction is of two steel webs of pressed steel, these being shaped with flanges at the peripheries, and riveted together. The two flanges when the plates are united form a rim, and on this is installed a hickory felloe, and this in turn retained by an outer rim shrunk on and by rivets through the rim, felloe and flanges. The wheels that were subjected to the test were 28 inches diameter, the web plates being 24 inches diameter. These plates were of steel .125 inch thickness and were formed by having a centre hole or opening for the hub 3.25 inches diameter. The web is perfectly flat for a radius of 4.75 inches from the centre, and from this to a radius of nine inches, where the inner surfaces of the plates converge, the surface is at an angle. Then to a radius of 11.875 inches the plates contact, and at this point turn outward to form a right angle, the thickness of the plate forming the remainder of the full radius of 12 inches. The greatest width of the flange is 1.625 inches.

From the opening for the hub, 3.25 inches diameter, for a radius of 3.125 inches, the space between the plates is filled with a circular block of hickory wood that prevents the web distorting under pressure when the hub plates are bolted on. The block is 9.5 inches diameter and 2.75 inches thickness. The surfaces of the webs that are in contact are securely fastened with a double row of rivets, and to the flanges of the webs a hickory felloe 1.75 inches is applied, this being secured by the shrinking on of a .25-inch steel rim, the flanges being 1.5 inches width, and the felloe and the steel rim 3.25 inches width. The assembly of the felloe and the steel rim are completed by riveting. The

thickness of the wheel, at the centre, before the fitting of the hub, is three inches. The web flange, the felloe and the steel rim are .25 inch wider than the centre.

Disc wheels are not an uncommon construction and are frequently used both in this country and abroad, but this particular design is claimed to have qualities not obtaining in others. Comparatively light steel plates are used, which are given the required strength for resisting distortion by the circular block of wood at the centre, this block supporting the hub. The block, being enclosed, is not affected by climatic changes and ought to endure a very long period of time. The angle of the plates from the wood block to the point of contact of the webs is such that the construction may be likened to a truss, for the load on the axle is supported from all points. The riveting of the plates insures certain contact and equal support and resistance, and the flange has the strength of the web plate, but is reinforced by the felloe and the outer rim.

Some Advantages Claimed.

Among the claims of the inventor are that this wheel is not affected by heat or dampness, and it will not expand or shrink, that the influence of the hickory felloe deadens the vibrations, that it will endure stresses far beyond the endurance of a wooden wheel, and that protected by paint it will wear for years. But the principal result is the strength that will insure against accidents and loss of service in the event of skidding or other mishap. This wheel differs from the "built-up" wheel produced abroad in that it has a combination rim. Foreign wheel builders have constructed wheels of stamped metal, sometimes of discs and sometimes of the spoked form that are assembled with rivets. These have been designed with a purpose of securing lighter weight and sufficient strength, but one of the faults has been the wearing of the rivets and the plates or parts, so that the rivets sheared and the same result obtains as when a wooden wheel has

The Bending Test: At Left, Wood Wheel No. 1 Loaded to Maximum of 16,400 Pounds with 1.46 Inches Deformation at 16,000 Pounds; at Right, Indestructible Wheel No. 2 Loaded to Maximum of 25,400 Pounds with .60 Inch Deformation at 16,000 Pounds.

The Transverse Test: At Left, Indestructible Wheel No. 4, Maximum Load 39,575 Pounds, Deformation at 20,000 Pounds .775 Inch; at Right, Wood Wheel No. 3, Maximum Load 20,195 Pounds, Deformation at 20,000 Pounds, 1.26 Inches.

shrunk. Most, if not all, of these designs had metal rims, and experience developed the fact that a rim could be bent by a severe impact, in which event its use for a very short distance caused extreme wear on the tire.

When a wooden wheel is subjected to a shock of much severity, deformation and breakage results, but a metal wheel may be much distorted and yet can be restored to its original serviceability. The foreign "built-up" wheels have usually been of the spoked type, and the strains have been necessarily borne by the spokes and, primarily, by the rivets. Wheels of this form have been sometimes of welded sections and the fault of these has been the crystallization of the metal spokes close to the rim and eventual fracture. With a view of producing what may be regarded as uniformity of metal, cast steel wheels have been built, the purpose of the designers being to obtain sufficient strength with minimum weight. The use of steel melted in electrical furnaces has been productive of the best results, but proportioning of the castings has been found to have been a very material factor. Such wheels are of several designs, those with solid spokes and rims, hollow spokes and solid rims, hollow spokes and hollow rims, with the brake drums for rear wheels cast separately and cast integral, with partial webs and spokes of the "cored" form, and with the spokes regularly formed or fan shaped at the rim to afford greater strength and more evenly distribute the load and the road shock over the metal.

Testing Indestructible Wheels.

The tests of the Indestructible wheels were conducted by Prof. L. V. Ludy to determine the endurance under torsion stresses, and those for resistance to bending and crushing by Prof. W. K. Hatt, the former being director of experimental engineering, and the latter in charge of the laboratory for testing materials. The torsion test consisted of subjecting a wooden wheel and an Indestructible wheel to a constant vertical load of 10,000 pounds. The wooden wheel was of 28 inches diameter, being designed for service with a two-ton wagon. The Indestructible wheel was designed for a 1.5-ton wagon. The wooden wheel had 12 spokes, the dimension of each spoke at the entrance to the felloe being 1.75 by 2.25 inches. This wheel has a felloe 1.75 inches thickness and a

steel rim .25 inch thickness. The Indestructible wheel was such as has been described. Each wheel was fitted with a hub of standard type to receive the short shaft used. The weight of the wooden wheel was 81.5 pounds and of the Indestructible wheel 128.5 pounds.

There being no torsion testing machine in the laboratory of sufficient capacity to test the wheels to destruction

in the manner desired, use was made of the Master Car Builders' brake shoe testing machine, which is part of the regular equipment. This machine consists of a large cast iron drum mounted on a shaft to which is fitted a car wheel. The machine is so designed that any brake shoe pressure can be applied and the frictional resistance offered to the motion of the wheel can be recorded on a roll of paper. A steam engine gives any desired speed to the car wheel. In utilizing this machine for the tests the engine and the recording instrument were disconnected. The wheels in turn were mounted on the main shaft, clamped in position and subjected to a vertical pressure on the upper side of the wheel, by means of a brake shoe and suitably arranged levers, of 10,000 pounds. This pressure was chosen as that which would probably represent the possible maximum pressure to which the wheels might be momentarily subjected, when in service. A large wood beam was securely clamped to the side of the cast iron drum of the machine, which served as a lever for applying a torque to the wheel. A track jack placed on a platform scale, was so arranged that it was possible to lift the large lever, thus rotating the drum and shaft of the machine to which the wheel was securely fastened.

The wheel in each case was prevented from rotating by a steel cleat bolted to the rim, which came in contact with the end of the brake shoe bearing upon the rim of the wheel. In bolting this steel cleat to the rim of the wood wheel, two .625-inch bolts were used, and four .5-inch bolts were used for bolting the cleat to the Indestructible wheel. By determining the load on the platform scale, it was possible to compute the torque at any instant, to which the wheel was subjected. The first portion of the reading was taken with the lever 131 inches in length, while in the latter portion a length of 132 inches was employed.

How Readings Were Made.

Prior to any readings for record, a steel roller two inches in diameter was placed between the brake shoe and the wheel rim, immediately above the centre of the truck wheel. When in this position a pressure of 10,000 pounds was applied and the load on the scale determined, which would cause a slight movement of the shaft. This gave a calibration figure which was considered in the test work and which eliminated the

force necessary to overcome the friction and the weight of the lever. In conducting the test of each wheel, different loads were applied to the end of the long lever by means of the track jack and the corresponding angular movement of the rim of the wheel to the hub was determined. The angular movement of the wheel was measured at four different points on the rim, approximately at 90 degrees apart, at the top, bottom, right and left. In addition to determining the reading of the weight on the platform scale, readings were taken of the spring balance connected to the end of the jack lever, which indicated the vertical pull necessary to raise the end of the long lever. The following were the results obtained:

Wood Wheel.				
Reading No.	Corrected Load at End of Lever in Pounds	Torque Subject to Wheel in Inch-Pounds	Average Movement of Rim Relative to Hub at a Radius of 13 In. in Inches	Average Angular Distortion of Wheel in Deg.

In carrying out the test, it was developed that the testing apparatus was not of sufficient capacity to test the wheels to destruction. Little or no apparent damage to the wheels resulted. In the case of the wood wheel it was found that at a torque of 140,000 inch-pounds, the spokes were slightly bent, and were beginning to show a slight movement in the hub. It was assumed that at this torque the wood wheel had reached the safe limit. After subjecting the wheel to a torque of 272,000 inch-pounds, the slipping of the spokes in the hub was very noticeable, but the wheel did not completely fail. The indications were that the wheel would have carried very little more torque without complete failure.

The Results Obtained.

The results obtained from the test of the Indestructible wheel indicate that the maximum of strength was not reached, even though the torque of more than 280,000

inch-pounds was carried. In reducing the torque to zero after the maximum amount obtainable had been reached, a set of 0.3309 degrees was indicated. The conclusion is reached from the set resulted from the slight movement of the different parts of the wheel. The test did not damage the wheel in the least, so far as a careful inspection could reveal, and it was believed a fair assumption that the maximum load did not strain it beyond the safe limit. Assuming that the safe torque which the wood wheel would safely carry under the conditions is 140,000 inch-pounds, and that which the Indestructible steel wheel will carry under similar conditions, is 280,632 inch-pounds, and that these wheels be used on a motor truck travelling at a maximum speed of 15 miles an hour, the conclusion is reached that the safe horsepower which could be transmitted by the wheels would be as follows:

Capacity of wood wheel.....329.4 horsepower
Capacity of Indestructible steel wheel.....660.3 horsepower

Of practical interest is the recorded rim pressure as indicated by the running logs of these tests and the results, which are shown as follows:

The Service Load Test: At Left, Wood Wheel No. 5, Maximum Load 64,350 Pounds, Deformation at 20,000 Pounds .24 Inch; at Right, Indestructible Wheel No. 6, Maximum Load 107,250 Pounds, Deformation at 20,000 Pounds .08 Inch.

With the wood wheel there was a noticeable bending and slipping of the hub. The movement of the rim commenced increasing rapidly at 1550 pounds on the platform scale. The test was discontinued because of reaching the capacity of the machine. The force on the scale required to move the wheel and shaft, with 10,000 pounds pressure on the wheel, was 521 pounds, with a vertical pull on the jack lever of 5.5 pounds, and a roller bearing on the rim of the wheel.

With the Indestructible wheel there was a noticeable slipping of the rivets at a pressure of 2170 pounds. The force on the scale required to move the wheel and shaft, with 10,000 pounds pressure on the wheel, was 483 pounds, with a vertical pull on the jack lever of one pound and a roller bearing on the rim of the wheel.

As the torsion test exerted pressure upon the rim to a point that would probably never be reached in actual service, for the deduction as to power transmission will demonstrate this, although destruction was not resultant, the data are of extreme interest. Attention may be directed to the data on the movement of the rims, which indicate that while this was decidedly variant with the wood wheel, there was practically uniform movement shown by the test of the Indestructible wheel.

The second series of tests were of three wood wheels and three Indestructible wheels, each of the same size and construction as those described, the experiments being to determine the strength of the wheels under bending strains, the load being on one side of the rim, a transverse test, and a service position test, with the load carried vertical on the axle. Of these, those numbered 1, 3 and 5 were wood, No. 1 weighing without hub or

bushing, 44.5 pounds, No. 3 and No. 5 weighing as tested 63.5 and 70 pounds respectively, and those numbered 2, 4 and 6 were Indestructible wheels, No. 2 weighing without hub or bushing 90.5 pounds, and No. 4 and No. 6 weighing 112.5 and 119 pounds respectively as tested.

The first or bending test, with the load on one side of the rim, was intended to approximate the conditions of loading when a truck skidding sideways is suddenly stopped by the wheel coming into contact with some solid obstacle. For

this test the wheels were fitted with two centre plates and supported by a solid axle placed vertically in the machine. The load was applied to the rim on one side at a distance of 12 inches from the centre of the supporting axle. The deformations of the wheel were determined by measuring the distance up to the rim from a straight edge clamped to the axle and extending across the wheel parallel to it. The accessory fittings, disposition of the machine and the methods of loading were the same in the tests of both kinds of wheels.

In the transverse test the transverse strength and stiffness of the wheels were determined. The wheels were mounted horizontally in the testing machine and supported at opposite points on the rims by two knife-edge bearings spaced 26 inches apart. Plates one inch thick, six inches width and 12 inches length were placed between the rims and knife edges to prevent local failure at the supports. The load was applied to the centre of the wheel by means of an inch steel roller placed parallel to the knife-edge supports. The deflection of the centre of the wheel downward was taken by means of a deflection instrument reading to .001 inch.

For the service position test, with the load vertical on the axle, the purpose was to approximate the conditions that would be met with in service when a loaded truck is standing still. The load would be applied to the wheel downward to the axle. The wheels were mounted vertically in the testing machine with the tire resting directly on the weighing table. A short dummy axle was applied directly to the hub, a bushing fitting the hub and carrying the axle. A yoke of two side members bolted to a top or crown piece was arranged with the ends of the side members carried on the ends of the dummy axle. The downward pressure was applied at the top of the yoke, this being graduated to any desired maximum. The movement of the rim with respect to the hub was read in four directions: Hub to top of wheel, hub to bottom of wheel, hub to right side of wheel and hub to left side of wheel. The method of applying the test and mounting the wheel was the same in the case of both wheels tested.

The data obtained in these tests were as follows:

Bending Test, Wheel No. 1.

Load in Pounds	Rim Movement in Inches	
	Downward Under Load	Upward on Opposite Side

With the wood wheel at a pressure of 6,000 pounds a report indicating slipping at a point unknown was heard, and the special hub plate was bending. At 12,000 pounds pressure a second report was heard. At failure the wheel was warped downward at the hub and the rims. The felloe was split on the line of the spokes at both sides of the wheel midway between the supports.

With the Indestructible wheel at about 22,500 pounds load the metal in the webs and tire reached its yield point. A report was heard indicating slipping or beginning of failure. At failure the wheel was badly warped, the metal in the web plates and the tire having reached its yield point.

Set after release of load	2.15	.02	.14	.16

The wood wheel was supported at the tire at a place semi-distant between two spokes. Up to 25,000 pounds the deformation was entirely a flattening of the rim between the two bottom spokes. The maximum load was 64,350 pounds. Up to a load of 25,000 pounds the rim flattened out between the two bottom spokes, but after that load was reached the spokes were in more direct compression. The two bottom spokes finally failed in compression at the maximum load. The rim pulled away slightly from the spokes on both the right and left sides of the wheel.

With the indestructible wheel the rim and the tire began to flatten at the bottom point of contact at about 15,000 pounds. At a load of 40,000 pounds the flat spot on the tire was five inches length, and at 64,350 pounds the flat spot was 7.5 inches length. The maximum load was 107,250 pounds and the deformation from hub to tire was carried to 2.7 inches. After the load was released the flat spot of the tire was 16.5 inches length. The failure of the wheel was the flattening of the felloe and tire 16.5 inches. The web plates were crushed down

through the felloe and then buckled outward and one web rivet was broken. The felloe bulged outward on each side, right and left, breaking 12 rivets in tension.

The comparison of the tabulations shows the relative strength of the wheels, and that the crushing of the wood felloe was the initial cause of failure, although the buckling of the web plates followed. Assumedly one point of the composite wheel was as strong as another, but the weakest part of the wood wheel was selected—that being between the spokes.

WHERE SALESMEN ARE TAXED.

A great deal of valuable information relative to the conditions that must be met by salesmen traveling in South American countries can be procured in the report on "Commercial Travellers and Samples in South America", which can be obtained for five cents a copy from the superintendent of documents, Government Printing Office, Washington, D. C. Remittance must not be made in postage stamps. The license taxes usually imposed in these countries, the amounts, conditions in which samples may be temporarily admitted free of duty, and suggestions of decided benefit are included in this report.

TRUCK WIDTH LIMIT FIXED.

The city council of Providence, R. I., has enacted an ordinance limiting the width of all vehicles using the streets of the city, to seven feet eight inches, and permitting the commissioner of public works to issue permits for the temporary or constant use of vehicles of greater width in certain streets. This is an amendment of an ordinance that fixes the limit of load capacity at 10 tons, and assumedly no provision has been made for the transportation of larger loads under any circumstances.

EXCLUSIVE ELECTRIC GARAGE.

A garage intended exclusively for electric vehicles, both pleasure cars and service wagons, has been established by the Electric Vehicle Service Company, Saginaw, Mich., at Germania avenue and South Second street, where any form of attention required will be given. The garage has storage capacity for about 100 machines and it has equipment that will afford high class service and maximum efficiency at minimum expense. The company has installed a motor-generator of 30 kilowatt capacity and switchboard, and it now has facilities for charging 50 batteries in 24 hours. The garage has already a liberal patronage.

VULCO QUICK ATTACHABLE TIRE.**New Truck Shoe With Cushion Joints That Absorb the Rolling Strains.**

The claims made for the Vulco quick attachable truck tire, made by the Vulcan Rubber Company, Erie, Penn., are that this construction combines the qualities of the block, solid band and demountable types, these being based on the results that have been developed from practical tests. The simplicity, ease of application and endurance efficiency are factors of decided value. The tire is built to the S. A. E. standards, fitting the standard rim and fastening with the standard bolted-on flange. The tire is seated immediately on the felloe band, there being no extra rim or wedge rings used.

The metal base is formed of individual steel sections about six inches length, which are so spaced that the soft rubber may flow between. This creates a cushion joint between each section that absorbs the rolling strain and prevents loosening of the tread. This series of joints also insures ease of application, as the joints give slightly and the tire can be applied or removed by simply jacking the wheel. No special tools are needed. The metal sections are concave in form, which lightens the tire from 10 to 15 per cent., and also raises all the wearing surface above the side flanges.

The face of each individual section is honey-combed with expanding corrugations or holes. When cured, the hard rubber flows into these holes and is dovetailed when solidified. The holes in the sections extend crosswise and lengthwise. When the hard rubber has been cured into the holes the result is a compound waved surface, which has a double area union of hard and soft rubber, which has nearly double the adhesive strength. This tire is made in either band or block type and can be used either single or dual. The tire is the invention of C. A. Swinehart, who is well known in the tire industry. The statement is made that the tire has been given very complete tests with extremely satisfactory results.

The National Cartage Company, Detroit, Mich., has since Oct. 8 been using a four-ton KisselKar truck hauling steel for truss concrete construction, operating it constantly, the crew working eight hours and three shifts of men being employed. The length of the haul is 1.5 miles and the daily tonnage is about 79 tons. No repair or adjustment was necessary until early in January, and the work required then was of minor consequence.

Motor trucks will be shown at the annual exhibition of automobile vehicles to be made by the Portland, Me., Automobile Dealers' Association, which will take place in the city building in Portland, Feb. 9-14.

TRUCK SHOW AT DETROIT.**Large Display at Annual Exhibition and Unusual Interest Manifested.**

The department devoted to the display of service vehicles at the annual exhibition of automobiles at Detroit, at the Ford branch building in that city, Jan. 17-24, was of extremely large proportions as compared with previous years, and the attention devoted to this class of machines was surprising, even to those who looked forward with anticipation based on intimate knowledge of conditions. The show was local in the sense that the exhibitors were agents, but the attendance was drawn from all sections of the state and the adjacent parts of Canada, and the business men found much to occupy them in examination of the vehicles displayed.

The number of exhibitors was 10, but two of them showed three makes each, the total of different machines being 14. These included the Buick, Packard, Wagenhals, Federal, Universal, Studebaker, GMC (both gasoline and electric), Tribune, Star, O. K., International, Pull-More, Commerce and Kelly. Practically all of these were known, the Tribune, Star, O. K. and Pull-More being developments since the last show.

Of these the Pull-More is a novelty in that it is a two-wheeled tractor coupled with a frame mounted on two wheels carrying a body adapted for the special purpose used. It is built by the Pull-More Motor Truck Company, Detroit, Mich. The front section or chassis is mounted on springs, the frame carrying the motor, clutch, transmission and jackshaft, and from the jackshaft the power is transmitted by chains to sprockets on the forward wheels. The motor and transmission gearset are incorporated in a single assembly, with which is included the cooling, lubricating and steering systems, and the radiator, hood, tank and seat may be lifted so that the mechanism may be reached for examination or work. The motor is a four-cylinder type with cylinder bore of 3.75 inches and stroke of 5.5 inches, the clutch is a cone, and the gearset will allow three forward speed ratios and reverse. The machines are fitted with 34-inch wheels, shod with four-inch tires. The standard wheelbase is 117 inches. The vehicles are built with one and two-ton capacities. The chassis is coupled to the body by a hinged device that compensates for strains that might be caused by road conditions.

The Croce Automobile Company, Asbury Park, N. J., builder of Croce motor wagons and trucks, has elected the following officers: President, Samuel A. Reeves; vice president, Albert Robbins; treasurer and secretary, Harry A. Watson; directors, Samuel A. Reeves, Albert Robbins, Harry A. Watson, Charles R. Zarharias, Louis P. Croce, Richard W. Herbert, Samuel A. Patterson, John Steins and A. G. Arbrand.

USE AND ABUSE OF MOTOR TRUCK TIRES.

S. V. NORTON, sales manager of the truck tire department of the B. F. Goodrich Company, Akron, O., was the principal speaker at the January meeting of the Motor Truck Club of America, held in New York City, making the trip to the Metropolis to address the organization. His talk was of considerable length and it was illustrated by lantern slides that had been prepared to show not only the collection of rubber and its manufacture into tires, but the use, care and conservation of tires. The attendance was very large and much interest was manifested, a considerable number of truck owners being present for the purpose of learning first hand facts that might be of material value to them.

Mr. Norton impressed upon the gathering that the function of the truck tire was to promote traction, to cushion the mechanism and to minimize the vibration. He stated that while rubber for tire material had not been perfected and the possibilities of the material had not yet been fully developed, yet it was the best substance that was known to those who manufactured tires. After considering manufacturing he turned to the manner of tire use and by views illustrated the effects of excessive wear and abuse, and made suggestions how these can be avoided. He pointed out the results from overloading, fast driving, skidding, driving in car tracks, driving over bad roads, the use of rigid skid chains and similar devices, running with wheels out of alignment and general neglect of small cuts and abrasions. He showed that owners are too

careless of tires, first allowing their trucks to be under-tired to save expense, then using trucks intensively in violation of the normal requirements for which the tires are made. He stated that these abuses rapidly break down the tires, often rendering them useless, while there is yet in the actual structural material thousands of miles of wear.

Urges Frequent Inspection.

He urged that owners awake to the recklessness of their course, both in their own behalf and in fairness

to the tire manufacturers, who are as anxious as owners to make tires more efficient. In general he felt that at the outset a truck should be equipped with as large tires as practicable, rather than the smallest, and that speeds and loads be kept within rational bounds. He believed that if owners would frequently inspect their tires, maintain watch over the driving habits of their chauffeurs and consult the tire maker freely, longer life and better results would be obtained by all truck owners.

During the period when the members and Mr. Norton exchanged questions and answers much of the most valuable information came out. It met the views and problems of owners on their own ground. Among other ideas Mr. Norton expressed was that average speeds up to eight or 12 miles were most conducive to solid truck tire life and efficiency, but that speeds in excess of that were specially ruinous. He admitted that the effect of "trailers" on tires is as yet uncertain, due to lack of experience in this country, and agreed

At Left: Ruptured from Overloading. At Right: Failure from Neglected Cuts.

From Left to Right: Torn by Skidding of Faulty Braking, Scored by Stationary Chains, Worn by Driving in Car Tracks, Result of Wheels Out of Alignment, Damaged by Excessive Speed, Used on Bad Roads.

to undertake for the club a careful investigation of the idea in Europe and other lands where trailers and tractors are more commonly used. He was unable to discover any material difference in tire wear as between steel and wood wheels, but outlined that each type has some peculiar merits of its own.

As to anti-skid chains and similar appliances, Mr. Norton said they all wear tires badly, but if so applied as to permit holding, yet gradually crawling about the periphery of the tire, rather than staying in one place, the wear is distributed so as to cause little trouble. At least, such devices appear necessary to prevent skidding and till the constant experimentation now in progress shows a better way, will probably prevail.

Worm Drive and Tires.

One question asked had to do with the effect of worm drive types of transmission on tire wear, the point raised being that the additional dead weight on the axle might materially add to the wear, whereas load carried on the springs does not. Mr. Norton stated that his observation of worm drives had been that unusually long tire life had resulted, though he could hardly say just what the reason was. Cases of 15,000 to 20,000 miles on Pierce-Arrow trucks had been recorded by his company.

As to the preference for solid or pneumatic tires, he stated that the chief objection to pneumatics for trucks was the uncertainty as to punctures. Constant experimenting is in progress by tire companies, he said, seeking to learn just what the economical practice in this respect should be.

In connection with the discussion of dead weight on tires, as against weight hung on springs, it came out from R. M. Lloyd that one pound on the dead axle is equivalent in tire burden to four pounds on the truck above the springs.

Selling Without Tires.

The suggestion was made by Charles E. Stone that trucks could be practically sold without tires and the purchasers encouraged to select the shoes with the advice of the representatives of tire manufacturers. This manner of selling has been very generally adopted in Europe and has been favored by the buyers, who can secure precisely what they desire for tires and have whatever equipment will best serve their requirements, for working conditions will vary greatly.

Apropos to the discussion, though not occasioned by it, Arthur J. Slade, consulting engineer, read a decidedly interesting paper on the influence of vehicle design on tire economy, maintaining that many factors in tire wear ought to be considered by the buyer who is seeking a machine, that the choice of that which will yield the largest measure of economy shall be made.

Prior to the meeting the statement was made by the officers that the incorporation of the club had been accomplished, that the working committees had been organized, that resources were larger than ever before, and that the 19 members admitted during the month had increased the membership to nearly 300. The

club has engaged as permanent counsel Ernest K. Coulter, whose advice may be obtained by members on all subjects with reference to their rights with motor vehicles.

DEERY LEATHER TIRES.

A leather tire specially suited to use of motor wagons and trucks has been patented by D. H. Deery of Bridgeport, Conn., which is claimed by the maker to have unusual qualities for endurance. The tires are made to fit any size of standard wheel rim and an average shoe is made of about 600 sections of chrome tanned leather pressed by hydraulic pressure of 5000 pounds to the square inch, which effectually consolidates it. The tire is retained in its form by a pair of half-inch steel rods that in turn are bolted to the rim.

The inventor claims that his tire is nearly as resilient as a solid rubber shoe and that it will yield about five times the mileage that will rubber. The leather is chemically treated and will resist water, while it is not susceptible to the usual influences that make for the deterioration of rubber. The maker maintains that the tires will give from 15,000 to 25,000 miles, according to the conditions in which they are worked, and that, being cheaper than rubber, they are decidedly more economical.

FOREIGN TRADE OPPORTUNITIES.

The consular report on foreign trade opportunities, issued by the Bureau of Foreign and Domestic Commerce, Washington, D. C., makes public the fact that at Madrid, Spain, there is to be public competition for furnishing three automobile chassis, the cost of each of which is not to exceed \$2700, for use by the fire department for carrying life saving and fire extinguishing apparatus; that in the United Kingdom a firm of engineers has requested information that will open correspondence with American firms manufacturing light, single-cylinder, two-stroke engines suitable for use in small parcel cars. Those desiring to do so can correspond with the office of the bureau, addressing No. 12,357 for the first opportunity, and 12,369 for the second.

The Maccarr Truck Company has been incorporated at Scranton, Penn., by C. H. Genter, E. S. Williams, F. L. Belin, J. J. Jermyn, R. G. Jermyn, R. E. Weeks, A. B. Warner and E. H. Connell. The authorized capital is \$125,000.

A department has been established by the Balknap Wagon Works, Grand Rapids, Mich., for the manufacture of motor wagon and truck bodies to manufacturers' or owners' specifications.

J. W. Dietrich has resigned the position of chief engineer for the Universal Motor Truck Company, Detroit, Mich. He has not announced his future plans.

NEW DEPARTURE PROGRESSIONS.

Administration Building Near Completion an Ideal Manufacturing Structure.

Within a few days the New Departure Manufacturing Company, Bristol, Conn., will occupy an administration building that is an ideal manufacturing structure. Erection was begun nearly a year ago. The building is six stories, including the basement, 220 feet length and 62 feet width, and is absolutely fireproof. The wall material is brick and tile and the main entrance is into a vestibule and a lobby that are admirable examples of architectural art.

The first floor of the building is given over to shipping and receiving, the second, third and fourth floors to assembling, and the fifth to offices, these being reached from the lobby by an electric elevator. At the front and south sides of the fifth floor are the private offices of the officials, these being divided by panels of mahogany carrying partitions of plate glass. At the west side is a double fire and burglar proof vault of two stories. The vault equipment is steel. Over the office is a leaded glass dome ceiling light 116 feet length and 16 feet width. There is a large foremen's conference room and a small kitchen on this floor. All office furnishings are mahogany.

The company will this year enter its second quarter-century. When first organized its business was transacted in a room less than 60 feet square; today its plant occupies nearly 60 acres, several millions are invested in machinery, operated by 2000 skilled mechanics, busy day and night much of the time. It is one of the most thoroughly equipped concerns in America. It has every facility for the scientific study of metals and the development of manufacturing processes.

Beginning Jan. 1, changes were effected in the company's organization which will further develop the plant's possibilities. Albert F. Rockwell, one of the founders, whose genius has developed the patents covering the company's products, has been relieved of much of the managerial details, but continues as president. DeWitt Page, who has been identified with

the company almost from its inception, and who has served in later years as secretary, sales manager, purchasing agent and advertising manager, has been appointed general manager. He is well known to the trade and is specially qualified for his duties. Charles T. Treadway, for a number of years treasurer of the company, continues in that capacity, with the added duties of chairman of the board of directors, and he will be an important factor in the future development of this remarkably successful enterprise.

S. A. E. MEMBERSHIP COMMITTEE.

The following membership committee has been appointed by the governing committee of the Metropolitan section of the Society of Automobile Engineers: Chairman, M. R. Machol; L. G. Busby, John R. Cantley, C. W. Flechter, Henry Van Riper Sheel, H. W. Slauson, J. E. Schipper, W. J. Sommers, E. R. Waterman, R. B. Whitman, A. M. Wolf and F. C. Wulf. This committee is making a campaign for membership and expects to increase the section considerably during the coming year.

WAVERLEY COMPANY'S OFFICERS.

The stockholders of the Waverley Company, Indianapolis, Ind., have elected the following officers: President, William B. Cooley; vice president, Herbert H. Rice; secretary, Wilbur C. Johnson; treasurer, William Kothe; directors, Hugh Daugherty, Joseph C. Schaf, Alexander C. Ayers and Hugh M. Love. The gross business for the fiscal year was \$1,312,815. The capital of the company is \$190,000, and including this and the surplus and undivided profits the company has resources of approximately \$590,000.

The Wasatch Motor Manufacturing Company has been organized at Salt Lake City, Utah, with capital of \$100,000, and a site of 10 acres has been purchased on which a four-acre plant is to be built. The intention of the company is to build trucks, but later on pleasure cars may be produced. The chief engineer and superintendent is George T. Smith, formerly general manager of the New York Mail Company. The officers of the company are: President, A. E. Young; vice presidents, John A. Maxfield and C. M. Fallas; secretary, J. B. Hamby; treasurer, R. E. Montrose.

Licenses to manufacture spark plugs under the Canfield patent have been granted by A. R. Mosler & Co., Mount Vernon, N. Y., to the Randall-Faichney Company, Boston, Mass.; Hampshire Manufacturing Company, Hatfield, Mass., and McCormick Manufacturing Company, Dayton, O.

The capital of Morgan & Wright, one of the subsidiary concerns of the United States Tire Company, has been increased from \$2,500,000 to \$5,000,000.

The Administration Building Shortly to Be Occupied by the New Departure Manufacturing Company, Bristol, Conn.

TO IMPROVE STREET TRAFFIC.

The Citizens' Street Traffic Committee has been organized as the result of a meeting of those interested in the improvement of street traffic conditions in New York City, which is to place information it may obtain at the disposal of the city authorities with a view to bringing about better regulation of highway use. The meeting took place at the house of the Automobile Club of America and was presided over by Robert Grier Cooke, president of the Fifth Avenue Association, which operates a line of motor omnibuses in Fifth avenue. The secretary was Elmer Thomson, secretary of the Automobile Club of America. In this movement the assistance of the Motor Truck Club of America was assured by President George H. Duck, and Harvey Robinson, secretary of the Electric Vehicle Association, offered the co-operation of that body. A deputy commissioner is to have supervision of the active work of the committee, and he will be assisted by a representative from each of the five boroughs of the city.

ELECTRIC VEHICLE BUREAU.

The United Electric Light & Power Company, New York City, has established an electric vehicle bureau, under the management of David F. Tobias, for the purpose of furthering the sale and use of electric vehicles in New York City and vicinity. It is the purpose of the bureau to co-operate with companies distributing vehicles and vehicle accessories, as well as with garages and owners of machines. The bureau is collecting transportation and operating data and purposes to interest the owners and users of horse equipment in "doing it electrically". The service of the bureau is available at all times to those in need of information, and may be obtained by addressing the manager at 1170 Broadway, New York City.

MOTOR WAGON PAPER DISTRIBUTION.

The Tampa, Fla., Tribune is a morning publication, and until recently its distribution, because of peculiar conditions, noticeably the absence of trains early in the day, was a problem that had never been satisfactorily met. There are a number of towns on the West Coast in which the paper could be circulated if delivered at a reasonable hour, but transportation was lacking until the paper purchased a Commerce wagon and used this for delivery of dealers' orders. Besides placing the paper in the different communities in season to develop material patronage, the cost of distribution has been considerably lessened.

Vibert S. Ross is manager of production of the Drednot Motor Trucks, Ltd., a Montreal, P. Q., company that has been reorganized and will continue the manufacture of Drednot trucks at 143 Welling street, in that city.

TIRE GUARANTEES REDUCED.**Five Makers of Truck Equipment Decrease Mileage Assured to Users.**

During the period between Jan. 2 and 9, five of the leading companies manufacturing solid tires for motor wagons and trucks announced a reduction of mileage guaranteed on all specified types sold following the announcements, with the understanding that adjustments would be made on all tires sold previous to the dates stated on the mileage guarantees in effect when purchases were made. That is, the reduction of guarantee would not be retroactive.

The companies acted independently, but the basis is now practically 7000 miles for a tire for a gasoline motor vehicle, to be used within a year, and 8000 miles for a tire for an electric vehicle, to be used within 18 months. The reduction does not affect all of the types made by some of the companies, for in a number of instances the guarantees were not uniform.

The Goodyear Tire & Rubber Company's reduction from 10,000 to 7000 miles was on the solid demountable, block, solid metal base and side flange types, these being placed on the basis stated, but no change was made in the guarantee on the hard rubber base type guaranteed for 5000 miles, on the solid clincher guaranteed for 7000 miles and the demountable cushion guaranteed for 7000 miles.

The B. F. Goodrich Company reduced the guarantee from 10,000 to 7000 miles on all gasoline vehicle tires, the guarantee to continue 12 months from date of sale, and on all electric vehicle tires from 10,000 to 8000 miles, the guarantee to continue for 18 months.

The Firestone Tire & Rubber Company reduced its guarantee from 8000 to 7000 miles on all solid tires for gasoline vehicles, to be used within a year, and placed the guarantee on electric vehicle tires at 8000 miles to be used within 18 months.

The United States Tire Company reduced its guarantee from 10,000 to 7000 miles on all gasoline vehicle tires, with a limit of 12 months for use, and on electric vehicles from 10,000 to 8000, with a limit of 18 months.

The Kelly-Springfield Tire Company reduced its guarantee of 10,000 miles for gasoline vehicles to 7000, with a year as the period of use, and on electric vehicle tires from 10,000 to 8000 miles, to continue for 18 months.

The reason for the reduction is stated to be the inability of the companies to continue guaranteeing mileage as formerly, and the belief that the owners will be impelled to bring about such changes in operation as will minimize tire wear.

The Midwout Motor Truck Manufacturing Company has been organized at Easton, Penn., with capital of \$500,000 to build vehicles, engines, etc., by J. C. Potts of Easton and P. L. Garrett and E. C. Boyd of Wilmington, Del.

URBAN ELECTRIC TRACTOR.

Machine with Three Tons Haulage Capacity Built by Kentucky Wagon Co.

In addition to its types of electric service wagons and trucks, the Kentucky Wagon Company, Louisville, Ky., has begun the production of a tractor that has a haulage capacity of three tons, which is intended for use in lumber yards or where animals have been utilized for placing of loads for convenient handling. It may be used practically for a number of purposes. The tractor is short, to facilitate easy operation in limited space, and at the rear is an extension on which the front end of a load carried on a two-wheeled reach is supported. The wheelbase of the tractor is 58.25 inches, but the overall length is 154.75 inches, and the tread 57 inches and the overall width 71 inches. As constructed the tractor carries the battery on top of the chassis frame, the forward end of the box supporting the seat for the driver.

The design of the machine is conventional. The motor is a General Electric type 1022, rated at 85 volts, 40 amperes, and 1200 revolutions a minute, which is installed transversely in the pressed steel frame just back of the rear axle, the motor being enclosed in a water and dust tight steel frame. The power from the motor is transmitted from the sprocket end of the armature shaft by a Morse silent chain to a sprocket incorporated with the differential assembly of the jackshaft, the chain and differential being enclosed, the chain running in an oil bath. The jackshaft is mounted on ball bearings and the drive is by side chains to sprockets on the rear wheels.

The controller is a continuous torque type and is installed in a case in front of the driver, and it affords four speed ratios forward and two in reverse. The frame is carried on semi-elliptic springs that are fitted with bronze eye bushings and the shackle bolts are hardened and fitted for grease cups. The axles are I section forward and rectangular section rear, the spindles being large, and the wheels are 32 inches diameter, equipped with Timken bearings. The tires are solid, four inches width.

The tractor steering gear is semi-reversible, a worm and nut type, the bearings being made large to insure against wear. The brake, operating on the rear wheels, is actuated by a pedal. The battery is 44 17-plate Hycap-Exide M V cells, which is sufficient to drive the machine through 10 hours' service. The speed is fixed at 12 miles an hour light and nine miles an hour drawing a three-ton load. The weight is approximately 4500 pounds. The machine can be turned in a radius of 15.5 feet. The platform on which the end of the load is carried is mounted on a pivot on the frame extension and the tractor can be driven so that the load when carried on two wheels can be turned practically in its own length. A rope carried through a sheave mounted under the end of the extension is

fitted with a hook at the end that can be hooked into the binding chain of a load of lumber, and this serves to tow the load. Release of the rope will permit the tractor to be driven free, so that the forward end of the load may be dropped or raised.

GOODYEAR CAPITAL INCREASE.

The stockholders of the Goodyear Tire & Rubber Company, Akron, O., will at a meeting March 3 act on a proposal to increase the preferred stock from \$5,000,000 to \$7,000,000, and common stock from \$5,038,000 to \$8,000,000. The proposition is that common stock to the value of \$1,500,000 be sold to holders of common stock, that \$2,000,000 preferred stock and \$500,000 common stock be sold to holders of preferred stock, both sales to be at par, and that the \$4,000,000 realized from the sales be utilized as new capital. The plan comprehends a common stock dividend of 20 per cent.

EXPERIMENTAL ROAD MAKING.

During 1913 more than 480,000 square yards of roads of different surfacings were constructed under the supervision of the office of public roads of the United States Department of Agriculture. The construction was in Arkansas, Florida, Georgia, Kentucky, Maryland, Mississippi, Nebraska, North Carolina, South Dakota, Tennessee, Texas, Virginia and Wisconsin and the District of Columbia. Since 1905 the office has supervised the construction of more than 4,000,000 square yards of road surface in nearly every state in the nation.

ADAMS BROS. COMPANY ELECTS.

The officers of the Adams Bros. Company, Findlay, O., chosen by the stockholders to serve the current year, are the following: President, Joseph J. Kwis; vice president, C. H. Bigelow; secretary, L. J. Adams; treasurer, B. B. Bigelow; purchasing agent, D. B. Adams; sales manager, J. T. Adams; general manager, W. D. McCaughey.

A three-ton KisselKar truck in the service of the C. G. Hartin Coal Company, St. Paul, Minn., fitted with a patent hydraulic body hoist, in one day, between 7 in the morning and 6:40 at night, delivered 79 tons and 1900 pounds of coal, this representing more than 26 capacity loads.

At a meeting of the Electric Motor Car Club of Boston, held at the Hotel Thorndike, that city, the evening of Jan. 27, the members listened to a statement of the plans for the Boston automobile pleasure car and motor truck shows, made by George D. Berry, assistant to Manager Chester I. Campbell.

SPARK PLUG MAKERS ORGANIZE.

The Association of Spark Plug Manufacturers was formed at Chicago, Ill., Jan. 29, this being the outcome of a preliminary meeting held at New York, the membership at that time consisting of 17 of the 35 firms manufacturing under Canfield patent licenses. A constitution was adopted and J. W. Fisher of the Silve Company was elected secretary and A. R. Mosler treasurer. A committee, consisting of R. E. Mills of the Rajah Company, R. A. Stranahan of the Champion Spark Plug Company, Albert Champion of the Champion Ignition Company, Emil Grossman of the Emil Grossman Manufacturing Company and E. M. Benford of the Benford Manufacturing Company, was named to investigate all matters relating to the spark plug industry, to report all infringements of the Canfield patent, and to consider and make report on all conditions that will be prejudicial to the interests of the industry as a whole or those using its products. Mr. Benford is chairman of the committee. Membership in the association is confined to individuals, firms or corporations engaged in manufacturing spark plugs or parts. The annual dues are \$25. The formality necessary for membership is signing the constitution and payment of dues. The office of the association will be located in New York.

BIG TIRES PREVENT SKIDDING.

The Indianapolis fire department has motorized apparatus in use which is utilized as in all other city departments, making as quick response to alarms as is practical with safety to highway traffic and the equipment. While making runs skidding on wet or slippery paving or street surfacings and when making turns was found to be a material source of danger. Different fitments were utilized with hope of minimizing skidding, and after experiment with chains and other devices to improve traction, increase of tire sizes was decided on. Accordingly a heavy ladder truck was equipped with pneumatic shoes 38 by eight inches, which were of the "Nobby Tread" type, and made by the United States Tire Company. These have been in use a sufficient length of time to justify an opinion as to their efficiency, and the statement is made by the driver of the truck that this equipment has practically eliminated skidding and the consequent danger. That the other motor apparatus of the department will be similarly tired is probable.

An example of the earning power of a motor truck when worked to full capacity is furnished by the records of the Cleveland Macadam Company, which show that its five-ton White dump truck, made by the White Company, Cleveland, O., used for hauling crushed stone, earned \$500 a month during a period of 4.5 months when it was possible to keep it moving all the time. The machine was loaded by a chute and dumped by the power of the engine.

ELECTRIC MEN INVADE SALEM.**New England Section, E. V. A. Promotes Interest in Haulage Subjects.**

The January meeting of the New England section, Electric Vehicle Association of America, the first of a series which will be held in cities in different parts of the states the organization represents, was at Salem, Mass., Jan. 15, the members giving over a considerable part of the day in a concerted effort to promote interest in the use of electric machines for both passenger and freight service. The section has inaugurated a policy which is expected to be productive of good results and to interest men generally engaged in business in the possibilities for economy in highway transportation. The purpose is to demonstrate the practical uses that can be made of electric vehicles, and to stimulate the local central stations to activities that will be productive of business.

A parade of a considerable number of pleasure cars, wagons and trucks was made in the afternoon through the principal streets of Salem, Beverly and the towns of Peabody and Danvers, and at 6 there was a dinner at the Salem Club. At 7:30 a parade of illuminated electric vehicles was made in the business section of Salem, and at 8 a meeting was held at the rooms of the Salem Board of Trade that was well attended. The visitors were welcomed by Mayor Hurley, and his remarks were replied to by Day Baker, treasurer of the Electric Vehicle Association.

Harry F. Thomson, engaged in research work for the electrical engineering department of the Massachusetts Institute of Technology, spoke to considerable length on the "Practicality of the Electric Vehicle", his address being illustrated by lantern slides. He sought to impress upon the audience that the electric car or wagon was in every way reliable, enduring and economical, and was suited to every purpose within its radius of movement. He was followed by Col. E. W. M. Bailey of Amesbury, by Frank J. Stone of the Electric Storage Battery Company, and by George W. Holden of the Edison Storage Battery Company. The chairman of the meeting was J. A. Hunnewell, chairman of the New England section.

The annual meeting of the B. F. Goodrich Company, which was to take place Jan. 21, because of the necessity of a full audit of the books, which could not be completed at that date, has been advanced to the third Wednesday in March.

The Union Ice Company, San Francisco, Cal., is now using 26 Packard trucks for haulage and distribution, having recently received 13 new machines.

The New Haven, Conn., Dairy Company has ordered two three-ton Universal worm driven trucks for immediate delivery.

Devoted to Motor Driven Business Vehicles of All Classes.

VOL. V.

PAWTUCKET, R. I., MARCH, 1914

No. 3

BOSTON'S THIRD NATIONAL MOTOR TRUCK SHOW.

Exhibition That Will Be Opened at Mechanics' Hall, March 17, Will Include 125 Different Types of Service Vehicles Produced by 35 Makers, Most of Them Fitted with the Latest Developments in Labor-Saving Body Equipment.

WHAT will be the only national exhibition of motor wagons and trucks of the year will be opened at Mechanics' building, Huntington avenue, Boston, at 8, the evening of March 17, and will be concluded the night of March 21, and it will be the third successive exclusive show of this character organized by the Boston Commercial Motor Vehicle Association, under the personal supervision of Chester I. Campbell. Extremely careful preparations have been made for the show and it will undoubtedly be the largest and best ever held in New England, and, for that matter, in America.

The present show was determined before the conclusion of the exhibition of 1913, and the preparations have been in progress for the past year. The announcement was made despite the abandonment by the National

Automobile Chamber of Commerce of the New York and Chicago truck shows, and the reason that impelled the decision was accurate knowledge of the business conditions obtaining in New England. There is no market in the world more promising than are the six New England states, which are a veritable hive of industry, and the need of highway transportation is absolutely imperative because of economic requirements.

The show was planned for a time when it would be possible for the business man from out of the city to combine a visit to it in connection with buying or other occasions for visiting Boston. Many of the smaller commercial centres have comparatively few agents or representatives of manufacturers, and a part of a day spent at the show will afford opportunity for obtaining information of all exhibits. From the viewpoint of economy of time of the Boston resident this is

a material factor, but when this is weighed by the visitor it is of even greater importance.

The show will attract many New Englanders from the fact that Boston can be reached from any point in a few hours. It will take place at the beginning of the period of the year when business activity is greatest, and when equipment must be

Mechanics' Building, Huntington Avenue, Boston, Where the Third National Motor Truck Show Will Take Place.

purchased. One of the features of the exhibition will be the attention that has been directed toward body production, for besides the standards stocked or furnished as regular equipment, there will be seen a very large diversity of special constructions intended to serve when quick loading and unloading is necessary to develop practical economy. There will be, in addition to these features, the differing improvements that have been made, generally as refinements and perfec-

tions of models that have been adopted as standard.

The number of different makes of machines that will be exhibited, so far as can be determined at this writing, will be 35, which will be shown by 31 different exhibitors, and the total of the vehicles included in these exhibits will approximate 120. This will be a much larger show than has ever been made exclusively of wagons and trucks, and the number shown by each exhibitor will range from one to 12. There is, however, probability that the aggregate will be somewhat increased before the show is opened to the public.

Going over the list of exhibitors it will be noted that with rare exception the displays are made by the agents or manufacturers' branches, and with but four exceptions all of the machines are those recognized as standards of the market. As a matter of fact but three are really new, one of the four being the product of a concern that has been reorganized and is to continue the production of the machines made by its predecessor.

Of the 35 different makes, 30 will be gasoline vehicle, four electrics and one steam, and of these five have never before been seen in Boston. Of the five, one is an electric and the others are gasoline. The new electric vehicle is the Andover, built by the Andover Motor Vehicle Company, Andover, Mass., and will be seen in 1000 and 2000-pound capacities. These machines are worm and gear driven and have been carefully designed and developed. One of the gasoline machines is the Walter five-ton truck, which is built under the Latil patents by the Walter Motor Truck Company, New York City, and is driven by the front wheels with metal tired rear wheels. This will be the first time this machine has been exhibited. Another new comer will be the Palmer-Moore 1600-pound delivery wagons, built by the Palmer-Moore Company, Syracuse, N. Y., and the others are the Twombly light wagon, built by the Twombly Car Corporation of Avondale, N. J., and the La Vigne light wagon, built by the La Vigne Cyclecar Company, Detroit, Mich. The Parcel Post Equipment Company, Grand Rapids, Mich., is successor to the Grand Rapids Motor Truck Company.

The display of accessories, equipment and supplies will be in keeping with the character of the show and will greatly interest all service vehicle owners.

The list of vehicle exhibitors is the following:

Andover—Andover Motor Vehicle Company, Andover, Mass.; one 1000 and one 2000-pound Andover electric wagon. Space 29.
Attisbury—Mattapan Motor Car Company, Mattapan, Mass.; one 1500-pound delivery wagon, one 1.5-ton worm drive truck, one three-ton truck. Space 113.
Autocar—Autocar Sales & Service Company, 642 Beacon street, Boston; one stripped chassis, four chassis with service bodies, one 15-passenger hotel bus. Spaces 115, 116 and 117.
Chase—Chase Motor Truck Company, Syracuse, N. Y.; one model D wagon, one model K wagon, one model R chassis and

one model O chassis. Spaces 26, 27 and 28.

Buick—Buick Motor Company, 95-99 Massachusetts avenue, Boston; one stripped chassis, four chassis fitted with service bodies. Space 5.

Couple-Gear—W. E. Eldredge, 221 Columbus avenue, Boston. Space 30.

Eldredge—W. E. Eldredge, 221 Columbus avenue, Boston. Space 30.

Federal—Whitten-Gilmore Company, 620 Commonwealth avenue, Boston; one model H stripped chassis, four model H chassis fitted with service bodies. Space 108.

Garford—R. & L. Company, 915 Boylston street, Boston; one two-ton truck, one three-ton truck, one six-ton truck. Space 110.

GMC—General Motors Truck Company, 753 Boylston street, Boston; one model VC 1.5-ton truck, one model SC two-ton truck, one model HU 3.5-ton truck, one model KU six-ton truck; all gasoline motor driven. Spaces 13 and 18.

GMC—General Motors Truck Company, 753 Boylston street, Boston; one 2000-pound electric truck chassis and one 12,000-pound electric truck chassis. Spaces 13 and 18.

Packard—Packard Motor Car Company of Boston, 1089 Commonwealth avenue, Boston; one two-ton chassis, one three-ton chassis, one four-ton chassis, one five-ton chassis, one six-ton chassis. Space 1.

Parcel Post—Parcel Post Equipment Company, 20 Green street, Cambridge, Mass.; Parcel Post wagons. Space 31.

Pierce-Arrow—J. W. Maguire Company, 745 Boylston street, Boston; one five-ton chassis, three five-ton trucks with service bodies, one two-ton chassis, two two-ton trucks with service bodies. Spaces 15, 16, 19 and 20.

Willlys Utility—R. & L. Company, 915 Boylston street, Boston; Willys Utility 1500-pound wagons. Space 111.

IHC—International Harvester Company of America, 43 Somerville avenue, Somerville, Mass.; water and air-cooled delivery wagons. Spaces 105 and 106.

Jeffery—C. P. Rockwell, Inc., 640 Commonwealth avenue, Boston; one 1500-pound wagon and one 2000-pound wagon. Space 107.

Kelly—Kelly-Springfield Motor Truck Company, 43 Somerville avenue, Somerville, Mass.; one Kelly one-ton truck, one Kelly two-ton truck, one Kelly 3.5-ton truck, one Kelly five-ton truck. Spaces 102 and 103.

Knox—Knox Automobile Company, 885 Boylston street, Boston; model S combination chemical, hose and fire pump; model M-3 combination hose and chemical wagon, model 31 Knox-Martin tractor, model 32 Knox-Martin tractor, model 31 Knox-Martin tractor adapted for fire department purposes. Spaces 8 and 12.

Lauth-Juergens—Myer Abrams Company, 159 Vassar street, Cambridge, Mass.; one one-ton truck, one two-ton truck, one three-ton truck and one five-ton truck. Spaces 131, 132 and 133.

La Vigne—C. J. Fischer Company, 222 Massachusetts avenue, Cambridge, Mass.; La Vigne light delivery wagon. Spaces 129 and 130.

Little Giant—Little Giant Truck Company of Boston, 221 Columbus avenue, Boston; 2000-pound delivery wagons. Space 30.

Locomobile—Locomobile Company of America, 700 Commonwealth avenue, Boston; one five-ton chassis, one five-ton chassis with demountable dumping body and one five-ton chassis with McGarry roller platform body. Spaces 13 and 17.

Palmer-Moore—Palmer-Moore Company, Syracuse, N. Y.; Palmer-Moore 1600-pound water and air-cooled motor wagons. Space 144.

Republic—Alma Motor Truck Company, Alma, Mich.; two one-ton Republic wagons. Space 36.

Reo—Linacott Motor Company, 163 Columbus avenue, Boston; one model H truck, one model J truck and one one-ton truck. Spaces 119 and 120.

Selden—Baker Motor Sales Company, 400 Massachusetts avenue, Boston; one model J truck, one model JL truck. Space 9.

Stewart—H. Ross Maddocks Company, Inc., 175 Pleasant street, Boston; one chassis, one model A truck, one model B truck, one model F truck. Spaces 24 and 25.

Standard—Whitten-Gilmore Company, 620 Commonwealth avenue, Boston; two three-ton trucks. Space 109.

Stanley—Stanley Motor Carriage Company, Newton, Mass.; one model 607 delivery wagon, one model 713 delivery wagon, one model 812 express wagon and one 12-passenger mountain wagon. Spaces 21 and 22.

Twombly—Twombly Car Corporation, Avondale, N. J.; Twombly light delivery wagons. Spaces 24 and 25.

Universal—W. F. Magill, 58-60 Brookline avenue, Boston; one model C chassis, one model A truck, one model K truck. Space 122.

Velle—Velle Motor Vehicle Company, 16 Amherst street, Cambridge, Mass.; one one-ton truck, one two-ton truck, one three-ton truck. Space 112.

Walter—Walter Motor Truck Company, New York City; one Walter five-ton front-wheel drive chassis. Space 138.

White—White Company, 930 Commonwealth avenue, Boston; four 1500-pound wagons, two 3000-pound wagons, two three-ton trucks, two five-ton trucks, one patrol wagon. Spaces 3, 4, 6, 7, 10 and 11.

Chester I. Campbell, General Manager, Boston Motor Truck Show.

REEVES IS GENERAL MANAGER.

Alfred Reeves, who was general manager of the American Motor Car Manufacturers' Association, and of the Association of Licensed Automobile Manufacturers, later sales manager of the United States Motors Company and general manager of the Hartford Suspension Company, was elected general manager of the National Automobile Chamber of Commerce March 5, succeeding Samuel A. Miles, who will devote all his time in future to the organization of the New York and Chicago automobile shows.

Mr. Reeves has had long experience with the office that he has resumed after an absence of several years, and he is one of the best known men in the industry. His knowledge and ability will no doubt add to the activities of the organization he is associated with, and the interests of the members will receive careful and prompt attention. Mr. Miles has managed the shows of 1913 and 1914 in New York, and he has directed all the shows in Chicago since 1902. Prior to that time he was interested in bicycle exhibitions. Under Mr. Miles' management the New York and Chicago shows have been exceedingly productive and profitable.

PEERLESS FIRE APPARATUS.

The Peerless Motor Car Company, Cleveland, O., has begun the manufacture of chassis adapted for equipment with fire department apparatus, and has designed a chassis with which horse engines may be converted to motor driven at comparatively small expense. Several of these vehicles are now in regular service and are stated to give excellent satisfaction.

NEW SERVICE MOTOR TRUCKS.

Three new models will be produced the present year by the Service Motor Car Company, Wabash, Ind., these being a different type than any previously built by this concern. The transmission of power in Service vehicles until these machines were produced was by the friction disc and wheel, so-called, but with these two driven wheels are utilized instead of the single wheel, which is the usual form.

The new models are of 3000, 4000 and 6000 pounds capacity, these being to very conventional designs and are fitted with Buda motors, Timken axles, Ross steering gears and a Warner gearset for the 3000-pound type and Timken gearsets for the two largest sizes. The drive of these machines is by double side chains.

HAULAGE BY SLED TRACTOR.**Novel Equipment Used by Knox Automobile Company in Snow-Filled Streets.**

With animals a snow fall of six inches is sufficient to materially impede traffic and loads must be reduced a third to a half, to say nothing of the greater time required for travel. With motor vehicles the machines can be driven in snow so long as the driving wheels can obtain traction, and the four-wheel driven truck will work more satisfactorily in deep snow than that driven by two wheels, the reason being evident enough. With heavy machines the rolling wheels will "climb" the snow and pack it beneath the tires, but the traction wheels, which are usually equipped with chains, cut through until a solid surface is reached.

During the heavy storms the last 10 days in February snow fell until it was 30 inches deep at Springfield, Mass., and practically every street in the city that was not kept open by the street railroad snow plows was obstructed for varying periods. In these roadways were broken eventually, but until this was done the use of nearly every form of vehicle was more or less impossible. Horses were used only with plows, and when the snow accumulated under the power wagons and they were in a sense converted into sleds, the bodies packing the snow beneath them and preventing the traction wheels reaching the ground, they, too, were unable to make progress.

The Knox Automobile Company used a Knox-Martin tractor in haulage practically all the time, during and following the storm, which was literally converted into a snow-tractor. Large shoes shod with steel and shaped to be clamped to the steering wheel of the tractor and the rear wheels of the trailer body were made and attached, and the driving wheels of the tractor were equipped with chains. Thus adapted the tractor was sent out into the deepest snow and good progress was made with capacity loads. The machine was easily controlled and traction was at all times sufficient, no matter what depth of snow it was in.

Knox-Martin Tractor, with Runners Attached to the Free Wheels, as Used by the Knox Automobile Company at Springfield, Mass., in Extremely Deep Snow.

HEXTER GASOLINE-ELECTRIC TRUCKS.

THE Hexter wagons and trucks, which were designed by Percy K. Hexter and are built by the Roland Gas-Electric Corporation, New York City, a concern that has been building machines commercially since last autumn, are, as the title of the company would imply, of the gasoline-electric type, the power being generated by gasoline motors and electric generators, and applied by electric motors, through jackshafts and side chains in the two larger sizes, and by shaft and worm and gear in the two smaller models. The purpose of the designer in using this method of power transmission is to obtain the highest degree of flexibility and to utilize the exact power necessary to drive the machines, rather than to adhere to the conventional gasoline motor driven vehicle with a limited number of speed ratios.

The Hexter designs are not experiments. The first machines produced were worked in every condition that could be found that would test their endurance and operating qualities. In every instance the results were gratifying and the company was organized for producing the trucks after a thorough demonstration of their qualities. The machines are constructed with the view of affording long endurance in the hardest service. The material is the best that can be procured and the workmanship is high class. The construction is with ample margins of safety, and with the minimized stresses when worked to capacity, because of the character of propulsion, the machines are expected to have unusually long life.

All Vehicles Have Same Characteristics.

The 1.5 and the 3.5-ton machines are identical in design, as are the five and seven-ton trucks, differing only in proportions of components. There are characteristics that obtain with all sizes, such as the use of a carburetor that is not adjustable, the use of ignition systems that eliminate hand control, the governing of all motors to specific maximum speeds, and the simplifying of the controlling system. In all these machines no clutch is used. The gasoline motor is coupled

to the electric generator, and this is driven to whatever speed is necessary to obtain a desired maximum power output from an electric motor.

This generator is built by the General Electric Company and is designed to have high efficiency and long endurance. It is a standard type of construction and has been abundantly tested in continued service. It is compound wound and designed to maintain a voltage as nearly uniform as is practical, so that increasing the speed of the gasoline engine does not, as might be expected with the ordinary dynamo, greatly add to the voltage, but the amperage is increased and the electric motor is supplied with a greater volume of current. That is to say, the potential is maintained within a specified range, but the amperage is widely variable, and this insures a sufficiency of power whenever it is necessary without exceeding the safe limit. The governing of the gasoline motor insures against excessive speed and protects the electric motor. At low engine speeds there is sufficient power generated to operate the vehicle wherever service may require. Like all well built electric motors, those used in Hexter machines are designed so they will endure under a very large overload for a brief period, and when occasion arises ample power is always available.

Change from Chain to Worm Drive.

The original Hexter truck was of 3.5 tons capacity, and this design is continued as the five and seven-ton types, and the most recent creation is the design of the 1.5 and 3.5-ton machines. The power plant and electric generator installation is the same in all, but a single motor is used in the two smaller vehicles. This motor is suspended in a sub-frame that carries the gasoline engine and generator, and the driving end of the armature shaft is coupled to the main shaft by a universal joint. The driving shaft extends to and drives the worm shaft and gear wheel mounted in the rear axle housing. The rear axle is a full floating type, the housing carrying the load, the driving shafts affording the traction only. With both of these ma-

Top View of the Hexter Gasoline-Electric Seven-Ton Truck, Showing the Location of the Generator Driven Motors, Each of Which Drives an Independent Jackshaft.

chines the drive is through the rear springs, which are shackled at the rear ends only.

The engine of the 1.5-ton machine is a Waukesha, with cylinder bore of 3.75 inches and stroke of 5.75 inches, a four-cylinder, water-cooled construction fitted with an automatic float feed carburetor, and an Eisemann single high-tension ignition system with a fixed spark. The fuel supply is controlled by a pedal, the purpose

being to prevent a sufficient volume being furnished the engine to cause it to race when idle, this being a protection for the generator. The generator is 7.5 kilowatt capacity. The 3.5-ton truck has a Waukesha engine of the same type with cylinder bore of 4.25 inches and stroke of 6.75 inches, but it is fitted with an Eisemann dual ignition system with automatic spark advance, and the fuel supply is similarly controlled. The generator is 7.5 kilowatt capacity.

Two Motors for Large Trucks.

The power from the generators of the five and seven-ton trucks is utilized by two motors, which are suspended in main chassis frame, one forward of and the other back of the jackshaft. The forward motor drives the right side of the jackshaft and the rear motor the left side, the jackshaft being in reality two separate shafts that are driven independently of each other. The pinion ends of the motor armature shafts carry sprockets which are aligned with larger sprockets on the driving shafts. Chain cases enclose the silent chains by which the jackshafts are driven, the chains and sprockets operating in oil baths. From the outer ends of the jackshafts, sprockets and chains transmit the power to the rear wheel. There is no differential, as might be inferred, and one motor may be driven as much faster than the other as necessity requires, affording equal traction no matter what the condition. The driving thrust of these machines is taken by radius rods. The power plants are larger and the generators are 12 kilowatt capacity.

As will be noted from the illustrations the design of the chassis is in every way conventional. The radiator is mounted in front of the engine, the gasoline motor is covered by a hood and is easily accessible. The chassis frames are of heavy steel channel section and these are carried on semi-elliptical springs. The axles are large and are fitted with anti-friction bearings throughout. The machines are driven from the left side, and the fuel control is by an accelerator pedal and the electric current is controlled by a hand controller that is exceedingly simple. The service brake is applied by a pedal and the emergency brake by a hand lever, both operating on drums on the rear wheels.

Power Control Exceedingly Simple.

The electric power control is by a controller handle located at the side of the driver's seat, that affords two forward speeds and reverse. The system differs

Side View of the Hexter Seven-Ton Truck, Showing the Conventional Appearance of the Construction.

from that of the battery driven vehicle in that resistance is not used, but the current is varied by use of different motor circuits. When the forward high speed is used the motor or motors are in parallel, and when in low forward speed or reverse they are in series. The speeds forward are not widely varied so far as vehicle movement is concerned, but the low speed affords much greater torque and consequently it is more productive of power in the event of ascending grades or in sand or rough road. The motors are arranged in series-parallel and they will endure the full output of the generator for 20 minutes before they will heat to a danger point. There is a neutral position for the controller handle in which both the motor and generator circuits are broken, and when so set the gasoline engine may be operated without influencing the electric power system. When operated slowly the generator does not generate sufficient current to be effective. Because of this fact the controller lever may be moved from one position to another without causing movement of the machine. Because of regulation by the foot accelerator the gasoline engine can only be operated slowly without its use, but movement of the accelerator will increase the speed to such a point that the truck can be moved with the controller in any of the three positions.

The gasoline engine is started by cranking, and from every aspect its operation is conventional. Its range is from the idling speed to the maximum allowed by the governor. In the low forward speed position the fuel consumption is most economical. The customary method of varying speed when in motion, unless the road is rough or sandy, or ascending a grade, is by change of engine speed.

The Roland Gas-Electric Vehicle Corporation builds chassis only, and the purchasers have body equipment constructed to meet their special requirements. The present capacity of the works is about 100 machines a year.

The Continental Motor Manufacturing Company has added 200 workers to its Muskegon, Mich., plant, which is extremely busy with the production of small types of engines.

C. P. Kiel is endeavoring to interest business men of Oakland, Cal., in a projected company to build a truck in that city.

CONTRACT STORE DELIVERY.

Equipment Having Private Ownership Appearance Provided at Cleveland.

The Delivery Company, Cleveland, O., which is now operating a large fleet of electric wagons and several gasoline trucks for general transportation and distribution in that city and suburbs, specializes in two directions. It will make contract to regularly deliver the goods of any store of any proportions on a basis of packages; it will make deliveries casually whenever orders are received, and it will furnish those who desire to operate themselves any type of vehicle desired, with driver, at a flat rental price for the month.

The company is now serving more than 200 different stores of the city and for a number of firms machines have been provided that have all the appearance of private ownership, being finished with panel bodies bearing the names of the firms using them, and decorations or lettering that have a distinct advertising value. Of course such vehicles are not utilized for any other purposes than those of the firms renting them, and being devoted exclusively to such service they are controlled as though they owned them. In some instances the drivers are uniformed.

When a machine is rented the price includes the service of the vehicle, the driver, attention, care, maintenance, and every detail of operation, the company storing the wagon in its own garage, having all work done by its mechanics, and systematically maintaining and operating it. The possibilities for keeping it in first class condition are much greater than were it cared for incidentally by a garage, or by a man with limited experience, the company's organization being developed with a view of protecting its property fully and giving its customers the best service that is practical. In the event of accident or mishap another vehi-

cle is temporarily supplied, so that there shall be no loss of time or service. The accompanying illustration shows a pair of Baker 1000-pound delivery wagons, with panel bodies, such as are used by the company for delivery or rental purposes.

CANNOT USE NAME "GRAMM".

The suit instituted by the Gramm Motor Company against Fisher & Co., of Walkerville, Ont., to restrain the respondent company from the use of the word "Gramm" in connection with the manufacture or sale of motor trucks has been decided by the court in favor of the complainant. The decision was to the effect that a perpetual injunction should issue, although the respondent maintained that the word at issue was generally used in the trade to designate a certain truck which both the defendant and plaintiff manufactured.

DIEHL MANAGING SALES.

William E. Diehl, manager of the Chicago branch of the American Hardware Company, has been appointed sales manager of the Corbin Screw Division of that concern and is now located at New Britain, Conn., assuming a part of the duties of Clarence A. Hart, who was, previous to his resignation to become vice president of the Hendee Manufacturing Company, Springfield, Mass., general manager and sales manager of the division.

S. A. E. SUMMER MEETING.

The details of the plans for the summer meeting of the Society of Automobile Engineers, which will take place at the new Cape May hotel, Cape May, N. J., June 23-26, have been practically determined, and according to the announcement the standards committee will meet the afternoon of

the first day. The business sessions will take place the afternoon of the second day, the morning and afternoon of the third day and the morning of the final day. The evening of the second day an entertainment will take place, and the following evening there will be a dinner and a lecture on the European trip projected for the autumn. The meeting will be concluded early the afternoon of the fourth day. The recreation grounds of the hotel will be open to the guests and various amusements have been planned in connection with the outing.

Type of Baker Electric 1000-Pound Wagon, Equipped with Flare Board, Screen Express Body, Utilized for General Purposes by the Delivery Company,

PALMER-MOORE 1600-POUND DELIVERY WAGONS.

THE Palmer-Moore Company, Syracuse, N. Y., is now producing two types of chassis, the one standard air-cooled, two-cycle, three-cylinder motor, and the other with an engine of the same design that is cooled by a thermo-syphon circulation of water. The motor has been built for several years and is well known from the fact that it has variable ports, this making possible the variation of the supply of fuel and the power production of the engine. The cylinder bore is four inches, and the stroke four inches, the motor being rated at 28.8 horsepower. The air-cooled type has been utilized for service vehicles and has been found to be specially reliable and enduring. The water-cooled motor was developed to meet the demands of those who prefer that type of engine and it has all the characteristics and qualities that have been peculiar to the Palmer-Moore motor.

The design of the Palmer-Moore motor is something out of the ordinary, it being maintained by the manufacturer that it is the height of development of the two-stroke cycle engine. The cylinders are cast separately with wide horizontal external flanges or fins about the expansion chamber, and vertical flanges about the head. The combustion chamber is spherical so that the gas is always ready to fire freely and there are no angles on which the products of combustion can accumulate and create carbon. One of the features of the construction lies in the oil ducts that extend from the base of the cylinder in the walls to a point just below the top of the piston when at its lowest point. These ducts are never opened at the upper ends, but they are always filled with a mixture of gasoline vapor that is permeated with oil (the same as that consumed as fuel), and this lubricates the walls of the pistons, the cylinders and the ends of the wristpins, affording positive lubrication and insuring against loss of power. The pistons are constructed with air chambers at the heads, which prevent the heat from combustion overheating the piston heads and the piston rings and wristpins.

A distinctive feature of the Palmer-Moore motor is the valve construction. Instead of the usual form of inlet ports, which are constant in two-stroke cycle engines, the fuel is admitted through ports that are fitted with rotary shutters that are connected with linkage and set at any desired position for the immediate requirement. The ports may be so varied that the motor will have the exact volume of fuel to do a work, and the speed may be regulated

without causing irregular explosions or back-firing at low engine movement, or loss of power at high velocity. In other words, precise control is afforded by varying the opening of the inlet ports, and the operation of the motor is at all times smooth and even.

When operated in normal conditions and for ordinary work the motor can be best used at from 600 to 700 revolutions a minute, but should there be occasion the speed can be increased to 1000, which is a reserve for climbing grades, rough roads, sand, or where special power is essential. The statement is made that the design of the ports is productive of large fuel economy and there is all the advantage of a low speed engine, minimizing the wear on all bearing surfaces and reducing the probability of overheating. Another factor is the lessened noise of operation. The vibration is also correspondingly reduced.

When operated in normal conditions and for ordinary work the motor can be best used at from 600 to 700 revolutions a minute, but should there be occasion the speed can be increased to 1000, which is a reserve for climbing grades, rough roads, sand, or where special power is essential. The statement is made that the design of the ports is productive of large fuel economy and there is all the advantage of a low speed engine, minimizing the wear on all bearing surfaces and reducing the probability of overheating. Another factor is the lessened noise of operation. The vibration is also correspondingly reduced.

The motors are protected with French type of hoods, which afford access to all parts when raised, and every working part is easily reached. The motors are constructed to endure in continued hard service, having four main bearings, each 3.5 inches length, this giving 14 inches of bearing surface. The connecting rod bearings are 1.75 inches length. The bearings are all die cast from a fine quality of anti-friction metal.

Palmer-Moore Water-Cooled Delivery Wagon Chassis Fitted with a Four-Port Express Body, Having Capacity of 1600 Pounds.

and are unusually well protected by lubrication. The motor is lubricated by mixing oil with the gasoline, but grease cups are provided for the main bearings as well. The ignition is by a Bosch high tension magneto with a fixed spark, so that there is no other control necessary in engine operation than adjustment of the fuel supply throttle.

The claim is made for the Palmer-Moore that it is extremely simple, that the moving parts are minimized, that the endurance is very long, that it requires minimum attention to insure maximum efficiency and power productiveness, and that it has all the steadiness and pulling power of a six-cylinder machine.

The clutch is a three-plate type, with a steel centre plate that is mounted between two fibre discs. The design is such that the engagement is always easy and positive and it does not drag when being released. It can be slipped without damage or excessive wear. It may be used with equally good results either dry or lubricated. The adjustments are simple and positive

The Water-Cooled, Two-Cycle, Three-Cylinder Power Plant of the Palmer-Moore Delivery Wagons.

and the discs can be used until worn through. The drive is through a planetary gearset having two forward speeds and reverse, or a sliding gear gearset giving three forward speeds and reverse, the driving shaft having two universal joints between the clutch and the gearset, with a self-aligning ball bearing between the flywheel and the universal joints. The gearset case is assembled as a unit with the jackshaft, the jackshaft housing being mounted in heavy hangers, with the service brake drums on the outboard ends.

The radius rods have three swivel joints, so that there can be no strain on the chassis, but the driving thrust is constantly taken and the axle relation preserved.

The pressed steel channel section frame is mounted on semi-elliptic springs carried on I section axles having 1.75-inch spindles. The wheels are the usual artillery type carrying 36 by 2.5-inch tires forward and 36 by three-inch tires at the rear. The steering

gear is an irreversible construction with a single lever on the hand wheel, and centre control levers for the changes of speed and the emergency brake. The service brake is operated by a pedal and the bands contract on drums on the jackshaft 10 inches diameter and two inches wide. The emergency brake shoes are internal expanding in drums on the rear wheels. The capacity of the chassis is rated at 1600 pounds. The wheelbase is 102 inches and the tread 56 inches. The weight of the chassis is 2300 pounds. The gasoline capacity is 12 gallons.

The materials used throughout the machines are high class, carefully selected for the purposes used, and specially adapted wherever necessary. Special attention has been given to lubricating all the wearing parts, and means have been provided so that adjustments can be made or compensation made for wear whenever necessary. In service the machines have given excellent satisfaction. The chassis are fitted with differing forms of standard stock bodies, or the purchaser has the option of having special equipment built to suit his own purposes.

GMC TO LIST MORE STOCK.

The listing committee of the New York stock exchange has received application from the General Motors Company for the listing of additional voting trust certificates representing \$714,000 par value common stock and \$583,000 preferred stock issued since the last application in 1911, and to list from time to time \$3,374,200 common stock and \$3,036,000 preferred stock now held in the treasury, on notice that the stock has been disposed of. This includes a total of \$4,088,200 common stock and \$3,619,000 preferred stock. Of the amount first specified \$520,000 preferred and \$520,000 common stock was issued in part payment for outstanding capital stock of the Weston-Mott Company.

GOODRICH TIRE GUARANTEE.

The reduction of the mileage guarantee for solid motor wagon and truck tires recently announced by the B. F. Goodrich Company, Akron, O., was on the types with the wireless base and was from 8000 miles to 7000 miles, and not from 10,000 miles, as was inadvertently stated in the February issue of the MOTOR TRUCK. The guarantee is for use within 12 months.

The Acme Tea Company, Philadelphia, Penn., which operates a chain of retail stores, and which has a delivery equipment of motor trucks and wagons of different makes, has acquired two 3000-pound White wagons, being the first Whites purchased.

The plant of the Piggins Motor Truck Company, Racine, Wis., which concern is now in bankruptcy, has been purchased by E. N. McNab of Racine, and his intention is understood to be a rehabilitation of the business. No definite plans have as yet been decided.

CHARACTERISTICS OF TRUCK DESIGN.

Details of Improved Constructions Intended to Give Greater Accessibility and Endurance, Economy of Attention and Increased Efficiency in Service.

THE man investigating the qualities of motor vehicles that might be suited to a work, whether or not experienced, will necessarily estimate the rela-

made serviceable for years, and the usefulness would not end until the cost of maintenance became excessive. Motor vehicles have been used for much

The Combined Frame Cross Member and Spring Hanger of the Smith-Milwaukee Truck, the Spring End Guide of the Packard Machines, and the Shackle of the Light International Delivery Wagon.

tive values of the machines from actual or assumed knowledge of constructional details, and choice will no doubt be made after carefully weighing the different types without favor. That is, one can assume that a man buying a machine will endeavor to select that which, after careful appraisal, will seemingly have the most to recommend it. Few men will expect to find in any one machine everything that might be desirable. In fact the most skilled engineers will not agree on the value of applications, and for this reason it is impracticable for laymen to determine with anything like certainty what results are probable from varying applications.

There are those who will maintain that a single detail is sufficient to outweigh all others, or one factor may cause the rejection of a construction, and there are others who will measure everything by the price that must be paid. The machines that are found in the market are not as a rule completely tested through service, because actual determinations could only be reached by comparative work and observations extending over periods of time that would be equal to what is commonly known as the life of a machine.

Most engineers hold that a vehicle ought to endure for years if renewals are made when parts are worn to a point where failure might be anticipated. In other words, by restoration a vehicle could be

with knowledge from experience more satisfactory results will follow.

The prevailing belief is today that a gasoline motor wagon or truck ought to endure for five years with normal care and maintenance, and this prospect is based on what is believed to be good judgment. The majority of manufacturers will assume without hesitancy that any machine can be used in the widest varying conditions with economy for the length of time stated, while a few builders are inclined to base the period of serviceability on number of miles driven. The mileage is probably as accurate for estimating as time, and yet neither appears to be very definite. Yet when one considers the possibilities with any other utility the extremely wide variance with reference to usefulness is evident.

Improvements and Refinements.

The motor vehicle builder is in no different position than any other manufacturer aside from the fact that comparatively few can show a continuous experience for a period covering the usually accepted life of a machine with an unchanged construction. With

The Spring End Guide of the Packard Trucks, the Sliding Shackle of the Deaatur Suspension, and the Rod-Braced Spring Hanger of the Stegeman Design.

The Spring Saddle and Spring Clips of the Heavy Packard Machines, the Combined Spring Saddle and Brake Shoe Support of the Ward Design, and the Spring Hanger of the Adams Trucks.

rare exceptions some changes are made in design and construction, these usually being regarded as "refinements" or "perfections", and often of a character that appears to be trifling.

But in the majority of instances these so-called improvements are made with a view of increasing the wearing qualities, strengthening weaknesses and eliminating conditions that might result in premature failure, or at least insuring against causes that, if continued, would require excessive repair cost. Considering the changes in design from the viewpoint of the manufacturer it may be regarded that none is made except for a satisfactory reason. When a type is manufactured every detail must be provided for, and if production is made in considerable numbers manufacturing economy demands that machinery and other equipment be procured. If changes are decided on these must be made first in the engineering department and then in the production division, and in addition the vehicles in service must be considered and provision made for meeting with any requirements for their maintenance so long as they are in use. And for this reason when a material change is decided on it is usually the result of careful experiment and extended trial.

The character of improvement is decidedly important. It may be for the purpose of affording greater accessibility and minimizing labor that is necessary in attention and repairing, for reducing the wear, to better distribute stresses and obtain a more stable structure, to minimize possibilities of damage, to increase strength, to lessen weight, and to generally accom-

plish results that have a substantial purpose, these all having to do with structural endurance and longevity. Further than this are considerations equally satisfactory, providing for better lubrication, for economy of fuel, for convenience, for easier or more certain control, and, perhaps, appearance.

Designer Considers Chassis.

The designer of a service wagon or truck considers the chassis only, and so to a large degree the appearance is dependent upon the type of body that is installed, but because of the acceptance of general characteristics as desirable and the knowledge that this factor is often given material weight by probable purchasers, the engineer will seek to have his creation conform so far as may be practical with what are usually recognized as conventionalities of motor vehicle practise. This may be applied to the location of the dash, radiator, the form of the hood, shape of the fenders and different details that have no important bearing on endurance or service, and have no essential worth from any viewpoint, although these might influence a purchaser who attached the same value to them that one might establish in purchasing a pleasure car.

In estimates of motor vehicle value on the basis of design, obviously the quality of each detail must be understood. The first consideration is endurance, and this may be obtained by the use of material of high quality, or of sufficient proportions to resist the strains and stresses. The grade of metal is highly important when extreme strength and minimum weight are required, but so far as service machines are concerned

The Partially Housed Jackshaft Brake of the Walter Trucks, the Internal Expanding Main Shaft Brake of the International Wagon, and the Locomotive Type Jackshaft Brake of the Packard Machines.

The Combination Radius Rod and Chain Case of the Stegeman Truck, Adjustable by a Spherical Eccentric at the Jackshaft; the Bolt-Secured Jackshaft Sprocket of the Vulcan Design.

wheels, and the driving thrust is directed against the chassis frame by the radius rods or the torsion tube, as, with rare exception, the shackles swinging as the springs take up ends, and the thrust is that of the angle of inclination of the rods or tube. With light machines the rear springs are generally shackled, and with deflection as the springs are straightened the full action is possible, the shackles swinging as the springs take up or absorb the strain and really making possible a spring of the semi-elliptic form.

Because of the necessity of having sufficient spring strength to support a

load the action when a vehicle is light is exceedingly slight, and the road shocks are communicated through the construction almost to the same extent as if there were no springs. But under load the springs absorb a great deal of the vibration, this entailing almost constant action at the spring eyes and consequently a great deal of wear. The eye of practically any semi-elliptic spring is formed by turning over the end of the master or upper leaf, or perhaps the eye may be forged solid. As the spring is always tempered and will wear slowly engineers assumed that a spring would be sufficiently enduring, but experience showed that the bolts wore rapidly and when these were hardened the springs, which are much more valuable, wore, and so a compromise was made by the use of bronze bushings in the spring eyes which could be replaced when worn, which were in a measure self-lubricating, and when these were used with hardened bolts and fitted with grease cups the destructiveness of the spring action was largely overcome.

Strength of Components.

One purpose that is apparently shared by a majority of engineers is the making of components of such size that they will endure excessive strain, and vehicles of comparatively small capacity have the appearance of being unnecessarily heavy, but experience has taught that parts must be sufficiently large to resist every wearing influence. One may believe that the part itself is the only thing to be considered, but when one understands that breakage or failure may result in damage to other components, and that the whole assembly must be regarded rather than a single part, the wisdom of sufficient strength is apparent. The experience of many owners has been that constructions have been made too light and endurance has been sacrificed because of the supposition that weight might be saved and power economized. Not only this, with the very general inclination of owners to overload machines the strains and stresses upon constructions have been largely increased.

The traction effort of a motor vehicle is greatest in starting a load from a standstill or "anchorage", and with the usual form of drive this is exerted at the rear

load the action when a vehicle is light is exceedingly slight, and the road shocks are communicated through the construction almost to the same extent as if there were no springs. But under load the springs absorb a great deal of the vibration, this entailing almost constant action at the spring eyes and consequently a great deal of wear. The eye of practically any semi-elliptic spring is formed by turning over the end of the master or upper leaf, or perhaps the eye may be forged solid. As the spring is always tempered and will wear slowly engineers assumed that a spring would be sufficiently enduring, but experience showed that the bolts wore rapidly and when these were hardened the springs, which are much more valuable, wore, and so a compromise was made by the use of bronze bushings in the spring eyes which could be replaced when worn, which were in a measure self-lubricating, and when these were used with hardened bolts and fitted with grease cups the destructiveness of the spring action was largely overcome.

Where the springs are suspended by shackles that are simply side links, the simplest form of construction, the hardened bolts and bushed spring eyes meet all requirements for wear, these having the merit of durability and cheapness, but when a special form of shackle is required and the cost of these increases, the need of protecting them becomes a matter of importance, and this is frequently done by the use of bronze bushings for the eyes. In platform spring design the

The Locomotive Type Contracting Jackshaft Brake of Pope-Hartford Trucks, the Contracting Band Brake of the Reo Machines with the Sprocket Withdrawable Through the Drum, and the Combination Brake Drum and Sprocket of the Koehler Delivery Wagons.

The Brake Shafts and Linkage of the Croce Trucks, the Equalizing Device of the Adams Machines, the Brake Shaft Support of the Universal Worm-Driven Design, and the Brake Levers of the KisselKar 2500-Pound Wagon, Mounted on the Radius Rod.

purpose is to afford a universal action that will allow the side and cross members to be deflected equally and without strain, and the shackle blocks are necessarily subjected to a great deal of wear. These are usually fitted with bronze bushings and hardened steel bolts, so that by the renewal of the bushes restoration can be made.

The use of spring shackles is practically universal throughout the industry, but while these are in a sense necessary with front springs, because the driving thrust is exerted through the master leaves to the spring horns of the chassis frame, and the action from deflection or reflection must be compensated for at the rear end, in the heavier Packard trucks the rear springs are installed in guides that are bolted to the frame side member, these guides having a roll carried on a shaft between the two sides. The frame web is strengthened at the guide to insure against buckling. The ends of the spring are placed in the guide and above the roll, and as weight is added the deflection and consequent lengthening of the spring is permitted through the guides, the rolls preventing the spring

binding and insuring free action. The guides are the width of the spring and there is no side pressure, the chassis frame being supported at all times, sideway being minimized. In this construction, which is not new in wagon or motor vehicle practise, the master leaf is relieved from the excessive strain, and the pressure is more equally distributed. With this installation the spring is free from the thrust of driving, and while there is not the quick action that is to be found with springs connected with shackles, the results have been extremely satisfactory. The guides are well lubricated by grease cups and the spring ends are not subjected to wear, because the bearing surfaces are so large. One distinct advantage

is that there is never any lost motion from wear, the frame always resting on the wide spring and having this support at all times.

A construction that provides for a somewhat similar effect for lighter vehicles, and which seemingly has a great deal to commend it, first made its appearance

The Double Brake Shaft Bracket of the Standard Truck, and the Single Brake Shaft Bracket of the Selden Machines.

in the Decatur delivery wagon. This provides for the use of shackled ends that move longitudinally on horizontal guides with the deflection and reflection of the springs. For obvious reasons the guides are mounted outside of the side members of the frame, this increasing the width between the springs, lowering the cen-

Examples of the Installation of Helical Auxiliary Springs: The Axle Seat of the Vulcan Design, the Easily Removable Pope-Hartford Spring, and the Combined Spring Saddle and Seat of the Selden Wagons.

tre of gravity, and lessening the sideway and its attendant stresses.

Some of Its Advantages.

The practicality of the guide form of suspension cannot be questioned, and the results are decidedly satisfactory. The guides are of sufficient length to allow full deflection and reflection of the springs, and they are primarily of shallow yoke form, a solid bolt extending between the yoke arms. On this bolt, having a long bearing, is a short yoke. The bearing can be bushed with bronze if desired. The yoke can be moved slidably on the bolt. The yoke arms are transverse of the bolt and between them the spring is mounted with a bolt through an eye formed by turning or solid forging the master leaf of the spring. The best construction is with a bronze bushing for the spring eye. One of the advantages claimed for this construction is the "dampening" effect upon the spring movement because of the friction of the long yoke member sliding on the bolt of the guide, this making for easy movement and yet offsetting any strain, the position of the spring being maintained without stress, no matter what the distortion of the chassis frame.

shackle linkage is not constructed to endure extreme sideway, and when the shackles are of such length as will insure good deflection and reflection, the strain upon the links and the bolts is necessarily wearing. Obviously the shorter the links the stronger the construction.

PETTIT LEAVES COMMERCE COMPANY.

W. S. Pettit, who has been for a considerable length of time manager of sales of the Commerce Motor Car Company, Detroit, Mich., has resigned that position and is now taking a rest preparatory to making another association in the trade. He was advertising manager of the Studebaker Corporation before he became associated with the Commerce company.

NOT THE KELLY-SPRINGFIELD.

Considerable annoyance has been caused the Kelly-Springfield Motor Truck Company, Springfield, O., recently, through the publication of a statement concerning the Kelly Motor Truck Company of the same

The Auxiliary Springs in Lauth-Juergens Designs, the Single Forms for Front and Rear of Light Vehicles and the Front of the Heavy Types, and the Double Form for Rear Support Only—The Westinghouse Shock Absorber as Installed on the Front Springs of Walter Trucks.

The suspension adds materially to the flexibility of the frame suspension and eliminates any side pressure upon the springs, insuring the fullest resilient effect. This form of construction could be applied to the rear ends of the forward springs by offsetting the forward spring horns, and would minimize the side pressure in the event of the chassis being twisted. Seemingly this suspension would be advantageous with under-slung springs, in which the arc is much more pronounced and the length is greater, there being more sideway and consequently greater stress upon the springs between the spring seats and the shackles, this being a factor of considerable importance. While the "twist" of the spring is resisted by the attachment of the spring at the seat upon the axle, the strain is borne entirely by the spring clips, and these are occasionally broken by the combined effect of tractive effort and the excessive sideway, especially when a heavy load is carried. One of the greatest objections to under-slung suspension is the excessive effect of sideway, which is particularly noticeable when a load is not well distributed, and when vehicle is on a surface that has considerable crown. As may have been noted, the

city. The last mentioned concern, which has no active existence, and is liquidating, reduced its capital to \$5000, this being sufficient for the purpose of maintaining its organization until all claims against it have been settled. Many persons accepted the statement as referring to the former company, which has no connection with the other. The Kelly-Springfield Motor Truck Company has made no changes in its plans other than to prepare for an anticipated increase.

E. H. H. Fletcher, who was for more than a year in charge of the Stewart division of the E. V. Stratton Company, Albany, N. Y., has been appointed district sales manager for the Stewart Motor Corporation, being assigned to northern and western Pennsylvania, New York State and the provinces of Quebec and Ontario of Canada.

The fire department of Baltimore, Md., has purchased two three-ton White truck chassis, which will be especially equipped with apparatus to meet special requirements. The department now has 10 White chassis, eight of them fully equipped.

THE MOTOKART 400-POUND LIGHT DELIVERY.

THE Motokart, built by the Tarrytown Motor Car Company, which was recently re-incorporated with capital of \$500,000, is specially designed for those who have need of a small delivery wagon with practically unlimited radius of movement and moderate speed. The factory is at Tarrytown, N. Y., and the executive and sales offices at 1790 Broadway, New York City.

The Motokart is not a cyclecar. It is designed for delivery service, and is built to be economical of labor, of fuel, of maintenance and upkeep expense. While the weight is minimized, the machine has a wide margin of safety in its components, and ought to endure for long periods of time. The Motokart is intended for parcel delivery, for the service of the small business man who desires to afford his customers every convenience, or for the large business that has a considerable volume of comparatively small packages to deliver. The normal capacity is 400 pounds.

The weight of the machine is approximately 700 pounds, and its size is such that it may be housed in a store at the close of business. The design differs from the conventional in that the motor is housed under the seat of the driver, the forward portion of the chassis carrying the body. The seat may be entered from either side without inconvenience, which is a factor in saving the time of the driver. The seat is not furnished with a top, but this protection could be installed if desired.

The motor is a two-cylinder, four-cycle type with cylinder bore of 3.63 inches and stroke of four inches, and is rated at 10-12 horsepower. The cylinders are cast singly. The design is to standard principles and the lubrication is a combination of force feed and splash. The cooling of the engine is by thermo-siphon circulation through a large honeycomb radiator, which is stated to be efficient in all conditions of operation. The engine is accessible by removing the side panels of the driver's seat. The power is transmitted

from the engine by friction contact, the engine driving a large disc that in turn drives a wheel on a jackshaft, and movement of the driven wheel from one point to another on the face of the driving disc affords every ratio of speed. The power is transmitted from the jackshaft to the live rear axle by a single chain, this being positive and extremely flexible, so that with a constant speed of the motor the movement of the vehicle may be varied from four to 25 miles an hour.

The simplicity of the friction contact power transmission is such that any intelligent boy or man can be taught to operate the Motokart in a few minutes. The power can be graduated to meet any requirement, no matter what the grade or the condition of the road, and there is no possibility of damage because of lack of judgment. The method has been known and used for years with admirable success, especially with light vehicles.

The chassis frame is pressed steel channel section, and this is mounted on semi-elliptic springs, the driving thrust of the rear axle being taken by radius rods. The axles are of steel tube of ample size and the spindles, especially those of the steering knuckles, are unusually large. The wheels are of wire construction and are shod with 26 by 2.5-inch tires, these being of the non-skid motorcycle type. The machine is controlled by a vertical steering column and hand wheel located in the centre of the footboard, and by an accelerator and pedal that operates the driven disc. A hand lever operates the driven wheel on the jackshaft. The brake is actuated by a second pedal. The chassis is fitted with running boards and fenders, a tool box being carried on the left running board.

The chassis is fitted with both open and closed bodies, but the latter is usually provided, this being constructed of steel and is 51 inches length and 32 inches width and height. The wheelbase is 69 inches, the tread 44 inches, the overall length 106 inches, the overall width 52 inches, and the extreme height 52 inches.

The Motokart is extremely economical to operate, for while its mileage is comparatively large the fuel consumption is very small, the tire cost is trifling, and the other expenses are proportionate. The capacity of the vehicle is limited, but there are many thousands of business men, who for delivery, seldom send out a load that would be excessive for it. The price for which it is sold is less than would be paid in open market for an average horse and wagon, and the operating cost of the Motokart would be decidedly less.

The Standard Motokart Light Delivery Wagon Chassis with Open Express Body, Having Capacity of 400 Pounds.

LONG USE PROVES TRUCK UTILITY.

Well Planned Loading Facilities, Sane Driving and Consistent Maintenance Afford Practical Economies from Machines Serving Wholesale Grocery Routes.

THE provident business man whose attention has been directed to the possible economies of highway transportation is chiefly concerned in lowering the cost of the work he has to the lowest practicable point. Desire and sentiment are lost sight of in the endeavor to save money that might be regarded as needlessly spent, and so far as he is concerned his only purpose is to utilize the means that will insure to him the necessary work. There are those who regard appearance, but the practical man is often willing to sacrifice this if utility does not suffer, and there are few men who believe that work can be done constantly and paint and varnish maintained in the condition that it was originally.

The man whose haulage service is large has an entirely different condition to deal with than has the man whose equipment is comparatively small, and no one will take issue with the statement that the expense with the large service is less for each unit than where the units are few. When comparisons of the large and small installations are made, and perhaps similar types of vehicles are used in the same conditions, the difference may be marked, for, generally speaking, the results are proportionate to the character of administration.

The fact that the small transportation service costs relatively more than the large, however, is no reason why economy does not obtain, although it may not represent the minimum expense as measured by the results realized by the large installations. There are those who may believe that the cost of operating ought to be the same for each unit in use, assuming a stated expense for each, and that increase should be a progressive ratio, but there are numerous variables that are dependent upon circumstances and conditions, and are not governed by rule or standard.

Demonstration of Possibilities.

The change from animal to motor transportation equipment may be favored by those who have considered the subject carefully, but rarely is a service motorized without experimentation. The actual demonstration of possibilities is believed to be practical with the majority of business men, although few of them realize that the use of the single vehicle is actually

more costly, and that they seldom obtain maximum efficiency because of the lack of knowledge of the methods that will afford the best results. Firms that have large resources are not adverse to extended trials of motor equipment, and in many instances these have been made with perhaps a single vehicle, so one cannot say that this policy has not justification.

There are thousands of business men who have haulage requirements that necessitate the maintenance of equipment, and without question the subject of economy is always a consideration with them, but with rare exceptions they are adverse to purchasing because of the assumption that they cannot afford to make investment where there is the slightest uncertainty. They are willing to admit that others have utilized machines economically, but maintain that motor vehicles have

No. 1 Packard Truck That Has Been Driven 38,500 Miles in Three Years and a Half in Distribution for a Wholesale Grocery, with an Average Load.

not been sufficiently tried. Some base their judgment on their experience with pleasure cars, or point to instances where wagons or trucks were used with unsatisfactory results, not believing there was an excellent reason why the machines were regarded a failure.

Few men will willingly admit that their methods were responsible for the lack of efficiency. Experience has demonstrated that the majority will condemn a vehicle as an extravagance when no attempt has been made to utilize it to advantage, or it has been so used that maintenance has been costly. A reason very generally assigned is that "conditions are different", but conditions are often what the owners make them.

The value of example is unquestioned. Those who are investigating the utility of motor trucks and wagons may have greater confidence in facts that come within their range of observation, but service

No. 2 Packard Three-Ton Truck, That Is Driven 35 Miles a Day and Has Been in Service Three Years.

that has been extended over a period of several years cannot be regarded as experimentation. One can say with reasonable assurance that such experience ought to be particularly valuable, and from it deductions can be made that can be considered as established by practice. The experimental period has undoubtedly been passed and the service placed on what may be said to be as near a business basis as could be assumed.

For those who have need of delivery equipment that will serve an area within a 10-mile radius, carrying capacity loads a considerable part of the time and making emergency trips whenever necessary, the experience of the Lyons Delany Company, Pawtucket, R. I., wholesale dealer in teas, coffee and groceries, can be studied with extreme interest, for this covers a period of about three years and a half with one truck and nearly three years with another, these taking the place of animal vehicles. The results have been satisfactory as a whole, and yet the use of the machines has developed another aspect of delivery that is decidedly interesting to the business man. This does not mean that the trucks have not been efficient or enduring, but brings out the question of obtaining the largest economy that is possible in store delivery. And in this the attitude of the firm is that of best serving its customers and spending the smallest amount that is necessary for the work.

Lyons Delany Delivery Service.

The Lyons Delany Company is the development from a retail tea and coffee store established in 1876, and this led to wholesaling, later to dealing in spices and extracts, and eventually to groceries. The company still maintains a retail store for all save groceries. Delivery from this is comparatively small and is not considered in this article. The retail department is entirely apart from the wholesale division and the warehouse, which is located at 88 East avenue. The spice mill of the company is another department. For years the company dealt largely in teas, coffee and spices, its customers being all over southern New England. With the addition of groceries the volume of goods distributed materially increased, but outside of

the area stated these are sent by freight or express, and the delivery by trucks is to what may be termed locality custom.

The business of the company for which delivery is made is in Pawtucket, Central Falls and the towns of Cumberland and Lincoln on the north, where the furthest point reached is Ashton, about six miles distant, a portion of the town of East Providence, and the city of Providence and several villages in the town of Johnston. Of these Manton, about eight miles, is the farthest distant from warehouse.

The delivery is not made to a schedule, for conditions must be regarded, but the intention is to serve the customers as quickly as this can be done, for the business is necessarily competitive and considerable depends upon the rapidity of filling orders. The greater distance as compared with the Providence firms necessitates use of equipment that will minimize haulage, and this was one of the reasons the company decided to use a motor truck. The company did not propose to confine itself to the trade north of Providence, and with other conditions equal prompt delivery was essential to attract and retain custom. Because the business is so widely scattered a greater number of animal vehicles would be necessary than were the distribution made from the centre of the business section of Providence.

With First Truck Purchased.

The first truck purchased was a three-ton Packard machine which was equipped with an express body, this being built with a standing top with rack sides, with side and rear curtains, the driver's cab being a separate construction. When this was placed in service it was utilized for delivery in Providence and the more distant customers, animal wagons being used for the nearer deliveries. The use of the machine was given careful attention and to insure satisfactory efficiency its work was closely observed and record made.

With a single truck a garage was not considered, but contract was made with a local public service station for regular storage. The driver engaged was experienced in mechanical work, and while he was made responsible for the condition of the machine aside from results from normal wear, he was not required to devote a great deal of time outside of the working hours to attention to it. The service station specializes in repairing, and an arrangement was made whereby the machine was to be given whatever attention was ordered by the firm, the driver making report of the condition at the end of the day, and the foreman of the garage being instructed to note the operation of the machine when brought in at night that his advice

might be added to the observation of the driver.

The understanding of the owner of the station was that the machine was to be worked on whenever necessary so that it should be ready for service in the morning, and that meant that should there be occasion the garage men would work until a repair was complete and that there be a sufficient number to finish any undertaking when begun. In addition to this the garage was to make inspection of the truck to determine its condition. Later on, with the establishment of a Packard service station at Providence, the Packard system of inspecting was applied to the machine, and the company had the option of having its repair work done there or at the garage where the truck was stored.

The reliance upon the truck necessitated that it be always in condition for use so far as this could be provided for by foresight. The cost of operation was carefully noted. The work of the machine was two or more Providence trips with a Blackstone Valley delivery, the mileage averaging about 40 miles a day. The purpose was to carry a capacity load whenever possible, but instead of the work being based on tonnage the cost of delivery was figured on the basis of packages. That there might be practical uniformity of bulk and weight an average case of goods, or several small lots composing a single order assembled in a box or crate, was rated as a single package. Of course the weights varied materially, but this was believed as accurate a record as was necessary to arrive at practical results.

Location of Warehouse.

The warehouse fronts on a wide street, and there are no side or rear entrances. To load or unload without blocking the sidewalk, to escape delays that might result from traffic if goods were carried across the walk either to or from the truck, to have shelter in the event of heat or storm and to have the work of the men unimpeded, a loading stall was made that is approximately 25 feet depth and 10 feet width, the space being sufficient to house a truck with considerable spare room. Into this the truck can be driven on the level of the street. The floors of the shipping department and at the rear of the stall are at a height that is extremely convenient for handling the freight. In cold weather the doors at the front of the stall can be closed, so the workers are not exposed.

The shipping room is large and in this the orders are assembled in separate lots, the smaller being placed in bins for checking and packing, and the

others collected in separate piles. The layout was planned with a view of economizing the work of the shipping room force and the crew of the truck. The orders are made up each day for the afternoon delivery and the morning of the day following in the event of two deliveries, or for the entire day following should there be but one delivery. This applies to regular work and not to emergency or special trips.

Provision for Loading.

Regarding these facilities for a moment it will be understood that when the truck was put in service conditions for obtaining good results were much better than with the average place of business. The truck could be loaded or unloaded without loss of time of the men or the machine from any of the usual causes, and this meant that so far as the owner could control conditions this had been done, and the results with regard to time required for covering the routes and for delivery rested entirely with the driver. These were no doubt some of the reasons why the company found that the machine was economical.

Considerable attention was given to loading. The layouts of the routes were determined by the driver, who decided the order of stops, and with these the shipper arranged the loading, the freight being loaded in reverse of unloading, the plan permitting the shipping room force and the truck crew to handle a shipment very quickly. The policy of the head of the department is that all the help that can work to advantage should do the loading, this saving the time of the machine and better serving the customers.

Second Truck Acquired.

At the expiration of six months the company found that the economy of the first truck was such as to justify the purchase of the second. The quicker service, the larger capacity of the machine, the better satisfaction of customers, as well as possibilities for ex-

The Loading Stall in the Shipping Department of the Lyons Delany Company, with Entrance from the Main Highway, Insuring Against Delays in Handling Loads.

pansion all contributed to this decision, and the company took delivery of a second three-ton Packard truck. The same policy with reference to maintenance and care was continued with this, the belief being that there was economy in paying for storage at a public station rather than establishing a garage, equipping it and employing a mechanic to care for the trucks. Were the installation of considerable size the private garage would no doubt be a logical adjunct, but with the method of maintaining the machines the expense was decidedly less than with any other.

With the acquisition of the second truck one was assigned exclusively to the Providence routes and the other to those in Pawtucket and vicinity, and either is now utilized in the event of need for special work. The service is so arranged that the hours of loading do not conflict and neither machine is delayed at the warehouse, while each driver is expected to cover the routes in the quickest time that is consistent with the work to be done.

Each machine is driven an average of 35 miles a day, and this is maintained the year through. The No. 1 truck has been driven approximately 38,500 miles and the other about 32,000, or very close to 11,000 miles a year. This mileage is not extreme, but it is probably very close to the work that would be required with the majority of wagons or trucks.

Expense of Operation.

The records of the company show that with accurate figures as to overhead expense and to every detail of operating, which included the storage in a public service station and the necessary attention, the cost when the machines were the first year in service was about \$10.50 a day, or \$63 a week, but as the period of use has lengthened and the expenditures for repairs have become more the cost has increased to about \$12 a day, or \$72 a week. Considering the mileage, this expense figures roughly 34 cents a mile.

In discussing the trucks L. F. H. Delany, who directs the wholesale business of the company, says that from the viewpoint of the concern the machines have been satisfactory. He does not make extravagant claims for possibilities for work, for there has been no reason to make unusual mileage and the requirements have been reasonable. While it might be possible to make the same delivery with horses, the convenience and satisfaction obtaining with the machines would not be realized. The company has not materially extended the area in which it delivers to customers, but the trade has been given the fullest attention and the increased business has been provided for without extreme demands upon the vehicles or the men working them. The company has a single-horse wagon in service with which deliveries and general work is done, but aside from this the haulage is done with the trucks. Mr. Delany says that the machines have been worked rationally and never with the purpose of doing excessive volume of haulage.

Before the trucks were bought the requirements of the company were evident enough, and the first one

in service was naturally more or less an experiment, but careful observation and change of method soon adjusted any condition. The records first kept made possible exact knowledge of the work and a saving was found practical. He says that he might liken the machines to the installation of an elevator in a building. They cost money, just as any other modern requirement, but the convenience and the saving are evident.

The trucks have been kept in operation and have been worked in all conditions of the business with practical success. The results were equally good in winter and in summer, and aside from the use of chains in winter there was practically no difference in cost of operation. He does not believe in overhauling at intervals, but maintains that the trucks can be kept up with attention to the results from wear without withdrawal from service, for loss of time means expense in substituting other machines or horse wagons. He has found that as the use of the machines continues there is increase of expense of operation. The operating cost of the trucks at \$10.50 a day is considerably less than is estimated for average work, and the maximum figure is somewhat smaller than is usually allowed for machines of similar size, so it can be seen that with a comparatively small equipment the expense has been kept down by good management.

Cost of Delivery.

Mr. Delany says that he has carefully determined the cost of delivery on the package basis and he has found that the average is 10 cents, but he is not satisfied with this figure, for he believes that the greatest economy is not in reducing the delivery expense with reference to animal haulage, but in lessening it with whatever form of transportation is utilized. That is, he is just as desirous of economizing with the machines as he was with horses, and he does not care what form of transportation is used, provided that he can serve his customers to their satisfaction and obtain the results sought. Each time the cost is figured consideration is given to possibilities of still further reducing the delivery expense, but not at the sacrifice of the machines.

Relative to tire cost, Mr. Delany says that he has no complaint to make of the service he has obtained, and that he has found the tire manufacturers very fair in their dealings with him. Because of the heavy loads carried the four-inch dual shoes with which the trucks were equipped were removed and five-inch duals installed, and since the change was made the tires have worn well. He says that if a tire wears evenly he has no complaint to make, but if a shoe goes to pieces he asks for an adjustment and is given satisfactory allowances.

He says that the storage of the machines in a public service station has worked out excellent results. The drivers are expected to do their work on the trucks and they are not asked to devote themselves in overtime to repairing. They are capable of making whatever adjustments may be necessary and their re-

ports to the office are followed by instructions to the garage or to the service station to do whatever is needed. Of course the garage or the service station foremen may make additional report after examination, and if such is received authorization is given to whatever extent is believed desirable. No neglect of the machines is permitted, however, but work is not done without reason.

The arrangement of the loading stall was a development from necessity, as there is no entrance at the side or rear of the building from a street or alley, and carrying freights across the sidewalk would mean the loss of time of the trucks and the men, which in the aggregate would reach a very large sum. Backing the trucks to the building would mean blocking the walk, which the city would not permit. The location of the stall prompted the storing of the stock so as to convenience handling, and the shipping room is so laid out that the men can work to the best advantage.

Mr. Delany says that these details result from observation and purpose to do work conveniently, and not with regard to theory or science; simply common sense and the utilization of any idea that appears practical, and a willingness to try whatever appears to have merit. The period of experimentation with machines has passed and the company has minimized its records, for there is no need of facts that are absolutely established. Cost is the only need, because this is the basis of economy.

MUST HAVE FENDERS IN DETROIT.

The provisions of the city ordinance requiring that all motor vehicles used for service in Detroit, Mich., shall be equipped with a suitable fender are being enforced in that city, and the police are making complaints against the drivers and the owners of machines that do not meet with the requirements of the regulation. The probabilities are that the constitutionality of the ordinance will be carried to a higher court, or eventually to a determination. Aside from the cost of fenders, which is no inconsiderable item of expense, the experience thus far has been that the fenders are constantly being damaged and are not always operative when desired.

The Moody Compress Company, Galveston, Tex., has ordered from the General Motors Truck Company 10 electric trucks of six tons capacity, which will carry 25 bales of cotton each as a load. These machines are to be delivered as rapidly as possible.

The Federal Motor Truck Company, Detroit, Mich., now has as special representative Howard Wilcox, who was formerly president and general manager of the Standard Motor Truck Company, Detroit.

The Durable Dayton Truck Company has been organized at Dayton, O., with capital of \$25,000, by C. B. Foley, J. B. Ford and V. A. Troxell.

AMERICAN ELECTRIC CAR COMPANY.

Three Concerns Merged, with Capital of \$1,500,000, Plan Greater Activity.

The American Electric Car Company is the successor of Argo Electric Vehicle Company, Saginaw, Mich., Broc Electric Company, Cleveland, O., and Borland-Grannis Company, Chicago, Ill., these three concerns merging and determining plans for the unification of production and distribution, which is expected to result in material economy.

The Argo Electric Vehicle Company has been established for several years, with a factory and general offices at Saginaw, where both pleasure cars and wagons were built, the latter in a single type with capacities of 1000 and 2000 pounds. The machines have been generally distributed in the Middle West, where they have been regarded as satisfactory and dependable. A considerable number of its wagons are in service. The pleasure cars made by this firm are very numerous.

The Borland-Grannis company has built pleasure cars exclusively for several years, but recently a delivery wagon chassis with load capacity of 1000 pounds was designed, and this machine has been in experimental service. The results obtained have been very gratifying thus far and there has been understanding that within a comparatively short time these vehicles would be produced commercially.

The Broc Electric Company has built high grade electric pleasure cars in several designs for several years, there being a considerable number in service in Cleveland, O., and vicinity.

The officers of the American Electric Car Company are: President, F. A. Brand of the Broc Electric Company; vice presidents, Frederick Buck, Bruce Borland and U. B. Grannis; secretary-treasurer, Theodore Huss. The three concerns are now represented in the board of directors and the executive committee, and in addition to the assets of each concern, each financially sound, a considerable amount of new capital has been added. The purpose is to continue the manufacture of the cars without change of name and to market them through the regularly established agencies.

The reduction of overhead expense, the minimized expense of production in manufacturing and purchasing in larger quantities, the concentration of distributing endeavor, and the expansion of the market are expected to yield material return. Consolidation will make possible better and more careful exploitation of the service wagon field, in which large possibilities are expected.

At Hamilton, O., a company will build the new steel wheel invented by Thomas Sharp of Ludlow, Ky., which is adapted for use on service wagons. The wheel is a resilient type and is known by the name of Eureka.

LARGE TRUCKS FOR COAL HAULAGE.

Machines Productive for Even Short Hauls, If Worked Without Time Losses, for Capacity Loads, but Efficiency Lessens in Handling Family Orders.

OPERATING three five-ton, worm-driven Pierce-Arrow trucks, Olney & Payne Bros., the largest coal dealing firm in Pawtucket, R. I., after an experience with one machine for a year and a half, and with three for a year, has made conclusions as to the possibilities with motor equipment that are of decided interest to those who are engaged in the same trade. The trucks are used in combination with horse equipment and a comparison of cost has demonstrated facts that can be regarded as well founded, but, of course, the conditions must be understood and considered when these statements are applied.

Concretely, the machines have been proven to be economical in comparatively short hauls where they can be worked to anything like their capacity, but when conditions are such that their efficiency cannot be fully realized the saving lessens so rapidly that there is much

does a general business that requires regular and occasional distribution. The normal area in which deliveries are made is within a radius of three miles.

The company has delivered fuel long distances, making hauls of 20 miles in some instances, but for orders of this kind the cost of haulage is figured and the sales cannot be regarded as being influenced so much by competition as by the need of the purchaser and the willingness of the firm to accommodate. Work of this character is so casual, however, that equipment could not be maintained for doing it.

The company receives coal in barges that are unloaded by special equipment, the anthracite fuel being stored in pockets on the pier, and the bituminous being usually piled beneath an elevated conveyor. The yard is on filled land perhaps six feet above tidewater and the loads must be hauled up short but rather steep

grades to the office, and from that point in practically every direction grades must be ascended, some of which are of considerable length. While not apparent this is a factor of considerable importance, for the loads carried by any vehicles, and especially with animals, must be determined with reference to the grades, for obviously either they must be lighter than where the hauls are on level ground, or more time must be taken for making them. The fact that the yard has never been well solidified because of the character of the

The Three Pierce-Arrow Trucks Used in the Haulage of Contract and Family Orders by Olney & Payne Bros., Coal Dealer, Pawtucket, R. I.

greater loss than would result with less expensive equipment. The company has equipment that facilitates practically the same economies with animal vehicles as with motor trucks, and the real factor is time, so that every minute of the working day has a value. The main purpose is to make every minute productive, and with power wagons the necessity is emphasized by the larger cost of equipment.

Delivery Conditions.

The company has contracts to supply several large works with coal, which means that a part of the transportation department is busy with these deliveries practically all of the time. Generally, these customers are willing to have fuel delivered at any time and would prefer to have a considerable supply in the yards rather than take a stated quantity daily and have little or no reserve. Besides this the company

old river bed—paving has not even given satisfactory surfacing—and for a considerable period of the year is soft and badly cut by the heavy carts and trucks, precludes excessive loading.

Acquiring the Equipment.

The company purchased the first Pierce-Arrow truck for delivery in September, 1912, and for this a special body was built equipped with a power hoist. This was used for haulage of coal to the J. & P. Coats, Ltd., plant, a distance of slightly more than 1.1 miles, the round trip being about 2.25 miles. The work done with this was so satisfactory that a second machine was ordered, and this was delivered in February, 1913, the morning of the second day of a strike of union drivers. The strike continued for three weeks and the company hired a third Pierce-Arrow truck, and a Packard three-ton truck, both of which were fitted

with standard platform bodies. In this emergency two sons of members of the firm drove two of the trucks. During this emergency the machines were used for all kinds of delivery, for economies were not considered, and a third Pierce-Arrow was ordered, this being delivered during the strike.

The company offered 50 of its horses and a number of carts for sale shortly after the strike was begun and disposed of a considerable number of animals and vehicles. The reduction of horses and carts was necessary and the trucks were utilized in contract coal haulage so far as possible, and this work was continued throughout the winter until the trade had reached its least demand. The gear power hoists were replaced by the standard Pierce-Arrow hydraulic hoisting equipment, the change being regarded as necessary. When the contract haulage was not sufficient to keep all three trucks busy family deliveries were made with them, and as the dumping bodies are not generally useful in this service the driver was given two additional helpers, making the crew of the truck four, for the purpose of handling the loads as quickly as possible.

Comparatively few residences are built so that fuel may be quickly unloaded, and despite the use of chutes, bags or baskets and double the number of men the experience has been that the machines cannot be worked so as to show a saving as compared with similar work done with animals, although it is practical with full loads and efficient operation to do haulage at approximately the cost with horses. In other words, the trucks will show economies even with short hauls in contract work, and may be worked as cheaply as horses when full loads are hauled in family delivery, but the value of the load is too small and the profit not sufficient to justify the machines where the orders are small and the conditions for delivery are such that service time is lost.

In making this statement the facts that the company regards the endurance of the truck quite as much as it does its time, that overloading is not tolerated, and that the drivers are not permitted to drive fast should be understood. Both overloading and careless operation mean deterioration of the tires and mechanism, and if the period of usefulness of the trucks can be extended the company will profit in like ratio. Viewed from the policy of the company the life of the machines must be realized to insure economy, and if they will endure for greater lengths of time there is a decidedly greater saving from their use. This is the reason that prompts the

policy. By this is meant that the company has purchased the vehicles with expectation of five years' service. If they will endure each for six years the company has what might be considered as the use of a single vehicle for three years at practically no expense other than operation and maintenance, the principal fixed charges, such as interest on investment, depreciation, etc., having been provided for. Then with this concern the principal factor in determination of economy is the period of service, and while the builder maintains 100,000 miles is the probable life, all in excess of this is evidently clear gain.

The actual determination cannot then be made until the degree of serviceability of the machines is known, and this means, until they have ceased to have usefulness, although from another viewpoint, by consistent maintenance the life may be continued indefinitely. Then, in a sense, the period of experiment must be over a period of years and results cannot be anticipated.

The trucks are examined and given ordinary attention by a mechanic who has had experience with all the pleasure cars owned by the members of the firm for a period of 10 years, and whose competency is certain, but all repairs are made at the service station of the agent for the machines. The experience of the firm has been that most of the attention the engine needs is cleaning and sufficient lubrication, and the best results are obtained from prohibiting changes and experiment by the drivers or others. Wear in the other parts of the chassis may be compensated by the usual means, but normal adjustments do not affect the operation of the machine materially.

Wear of the Worm.

Because of the lack of knowledge of the worm and gear wheel drive the rear axle of each truck has been carefully observed whenever renewal of the grease packing has been necessary, and the worms and gear wheels have been closely examined. No wear has been

Loading Two of the Trucks Under the Trestle of a Conveyor by Machines Driven by Electric Power, a Work Minimized by This Equipment.

noted when the worms or gear wheels have been measured by calipers, but both the worms and wheels have been extremely polished, the surfaces of the metals having been more closely consolidated or "worn in" by the contacting. The milling marks have not been obliterated. To determine the probable wear in another way the grease removed from the axle housing has been analyzed and the results have shown merely a trace of bronze or steel particles, the volume, even with the wear of the differential to be considered, being negligible. That the wear was so slight was extremely surprising.

The purpose of the company is to have the machines carefully overhauled at the end of the busy season, and until that is done the actual cost of operation can only be approximated, for the expense for each is to be averaged for the operating period, so that there will be an actual monthly charge for overhauling made against each machine. In the same way the tire expense is averaged, this affording a decidedly closer knowledge of the operation cost than if the charges were made whenever the tires were renewed.

Provision for Loading.

In the operation of the trucks the constant endeavor is to utilize time profitably. Grades of streets are considered and routes chosen for hauls in practically every direction. In the yards three loading machines, electrically operated, are used for both anthracite and bituminous coal and for both horse carts and the trucks. To show to what extent conditions influence efficiency, a change of route necessitated by railroad improvement has increased the haulage in a very large contract so that the number of deliveries a machine can make has been reduced from 11 to 10, despite the quick loading and dumping, and another factor of importance is the weighing, for the trucks are weighed every time they enter the customer's yard with a load and leave it empty, and the weight can only be taken with the engine stopped. Conditions of this character must be considered, and they all contribute to the cost of operation, and lessen the productiveness. Factors of seemingly little importance have material bearing on operation of trucks, for in the aggregate they may decidedly influence results. With less expensive units the effect is relatively smaller.

The company has not as yet experimented with smaller units in delivery, although there is probability that there may be a saving with them as compared with what is now in service. Horse equipment units can be added to meet a comparatively small increase in business, but a much larger demand is necessary to justify the addition of a truck, for it could not be made profitable without work, or the animals and carts must be sacrificed when it is acquired.

While the company believes that eventually motorized equipment will be used in delivery, experience is necessary to determine what forms and capacities are best adapted for the work, and so far as its horses are concerned these will be worked until no longer useful, as this appears to be the only manner of realiz-

ing the fullest measure of their value without sacrifice.

The average mileage of the trucks is approximately 50 each day, although as much as 75 miles have been driven to meet some especial condition. The tonnage is variable, but in some instances it has reached figures in excess of 75 tons, and has several times exceeded 100. But these are not the rule.

NEW YORK TRAFFIC REGULATION.

Aside from London there is no city in the world in which the traffic congestion is greater at times than in New York, and the worst conditions are experienced in the main streets of Manhattan, extending north and south, in which the blocks are seldom more than 200 feet in length, while in the streets extending east and west the blocks are often from 600 to 1000 feet. An ordinance has been proposed and is now pending before the committee on general welfare of the board of aldermen of that city, which provides that all vehicles moving through any street running east and west shall stop before crossing any street running north and south. Now the movement of traffic is subject to the direction of the traffic police, and patrolmen are stationed wherever conditions assumedly demand them, so that a vehicle need not stop while crossing the streets extending north and south unless ordered to do so. The claim is made that with the long blocks of the cross streets there is no possibility of congestion from delay, and the proposed regulation would entail closer and better observation of conditions where there is danger, both for pedestrians and for vehicular traffic.

WANT TRUCK CRANES.

Interested manufacturers can obtain from W. & A. McArthur, 18 Silk street, Cripplegate, London, E. C., England, specifications prepared by the harbor board, Auckland, New Zealand, which requires one and two-ton truck cranes, mounted on chassis having rubber tires, assumedly for use in loading and unloading freight at the piers in Auckland. This information is supplied by the bureau of foreign and domestic commerce of the national Department of Commerce, Washington, D. C., and further detail may be obtained from this bureau by referring to No. 12,511.

The Firestone Tire & Rubber Company has completed its service station at West End avenue and 63rd street, New York City, where facilities have been installed to serve all owners of motor wagons and trucks using Firestone tires.

A branch has been established at Los Angeles, Cal., by Phineas Jones & Co., of Newark, N. J., well known as a maker of wheels, which is known as Phineas Jones & Co. of California, and is managed by H. Percy Jones.

ELECTRIC VEHICLE PRACTISE.

Need for Systematic Attention to Insure Obtaining the Maximum Capacity of Storage Battery Cells and to Minimize Deteriorating Influences--The Value of Records in Making Comparisons of Work and Efficiency.

By William W. Scott.

EMPHASIS has been made of the care necessary in charging and discharging battery cells, and that the best results can be obtained by following a formula, this insuring that the attention shall be uniform and that nothing shall be neglected. This is not intended to imply that the expert or the experienced batteryman is not dependable, but is intended to impress upon the reader that the highest efficiency can only be insured by applying such methods that errors are not probable and desirable standards are always attained. Neither should one assume that complications are resultant from use of a formula. To the contrary, when methodical attention is given, conditions are observed that can often be dealt with so that there will be no serious loss of efficiency.

Experience has always a certain value when results are of record, but guessing is sure to lead one into situations that may be serious, for these may be anything from loss of service to material damage. Battery cells will endure a great deal of hard usage from an expert battery engineer, who is qualified by training to deal with conditions that may be anticipated and provided for, but the one who is less experienced will not understand operating possibilities and in attempting what may appear practical enough cause damage, or what is equally serious, impair efficiency.

Satisfactory equipment for charging is imperative, for without this one must be guided more or less by guessing, and this may lead to errors that would not be probable were there the ordinary means for the determination of exact conditions. The experienced batteryman will often improvise apparatus that will serve in the event of an emergency, but this can only be used with extreme care and with full knowledge of what conditions will arise and what protection should be utilized.

As a battery is composed of a series of cells, and each is a unit with reference to voltage and amperage, that there will be some variance in the normal indication is exceeding probable. Theoretically, with the

element of each of similar material and the electrolyte mixed to a given standard, the cells ought to be precisely alike in specific gravity and voltage, but practically there will be slight difference even when the greatest care is taken.

The reasons for this are obvious. The electrolyte may be slopped from the cells in different volume and the loss will have some effect. The degree of loss from evaporation will vary because the cells will not be equally protected. That is, some will be more susceptible to the atmospheric influences than others, the vents will not serve precisely the same and the degree of gassing will differ because of the condition of the

DATE RECHARGE TAKEN WITH FLOW OR DISCHARGE FOR AMP. INSPECTION A.C. A.M.P. MILES		- FRONT -				BATTERY NO. MAKE TYPE PLATES A.C. TEMP. BATTERYMAN	
		CRATE NO.	CRATE NO.	CRATE NO.	CRATE NO.		

Fig. 1. Form of Convenient Record for Inspection of Battery of 40 Cells, Showing Arrangement of the Crates in the Box.

electrodes. The effect of the gassing is to dissipate the water of the electrolyte in considerable quantity and to carry off a small proportion of the acid. In any one cycle of charge and discharge the loss of acid is practically negligible, but in continued operation there is necessarily a diminution, and so from time to time "equalization", or a restoration of the volume of acid, is necessary to bring the electrolyte to the required density. These probable causes of variance are aside from those that might have material effect, such as a leaky jar, a broken separator, or a condition of any character that might be regarded as abnormal.

The first essential is systematic inspection that will be sufficient to detect the height of the electrolyte in the cells, and that will entail removal of the plugs

from the covers, observation of the condition of each in turn, and if there is any doubt the depth above the element can be determined by a strip of hard rubber or a glass tube about a quarter inch with square ends. The rubber strip or the tube may be marked with the normal height and any material difference will be precisely indicated. Dropping the tube into the electrolyte and touching the element and placing a finger on the open end, a depth will be shown by the fluid retained in the tube when lifted. Either of these will require a reasonable light, and if done at night an inspection lamp is desirable, for then work can be done about the cells.

Inspection may be done at reasonable intervals, and while conditions will often suggest necessities to the experienced batteryman when nothing abnormal is noted, good judgment would demand regularity in this work. That inspections may have the fullest benefit a systematic record is desirable, and this can best be made on a card that can be filed. Such a card is shown at Fig. 1 and Fig. 2, the former being for the smaller and the latter for the larger types of batteries. The use of such a card means the recording of the battery manufacturer's number, or the owner's number, the make, the type, the number of plates and, if this is practical, the average temperature of the period to which the specific record refers. As will be understood the entries aside from the temperature are constants. Referring to Fig. 1 one notes that this is for a 40-cell battery, with four crates of 10 cells each installed longitudinally in the battery box, which crates ought to be numbered, the odd numbers on one side and the even on the other, this being a convenient method of insuring the same position when replacing after removal from the box, as well as minimizing handling, for the outer crates must be taken out to remove the inner. Fig. 2 shows a card designed for a 48-cell battery, this having six crates, each containing eight cells, installed transversely in the battery box. Any one crate may be withdrawn at either side without moving any of the others. The same system of numbering may be applied to this form of installation. Obviously the crates should be marked plainly, the longitudinal type on the side and the transverse type on the end.

Referring to these cards, one will understand that each square represents a cell, and when the crates are placed in a battery box in a given position the cells, if not shifted in the crates, will always be in the same place. The value of this is shown in the record, for by the inspection reports an analysis can be made from the history of any cell, and a condition traced accurately. This information is of material value to the batteryman. Obviously, to systematically handle the cells requires no longer time than to handle them without system, and the possibilities for obtaining satisfactory results are proportionately greater. To illustrate, when a cell is always in one place in a crate and the crate is always in a given position, specific observation is more certain than if changes were made. This

makes practical the keeping of the records as well. As will be noted, the cards show whether the readings were taken on charge or discharge, the flow of amperes, the age of the battery, the number of miles driven, with the date, the name of the inspector and his assistant. In the square representing the cell the readings are noted. Thus one card will serve for an entire battery for each inspection. Comparisons of the readings will indicate the condition of each cell at each inspection, and comparisons of the cards will demonstrate the variance evidenced by the inspections.

The daily or regular charging should be of record, and where the desire is to keep this singly, with a view of entering it in a sheet that will extend over a given period, such as a month, this may be a simple form of a size that is convenient to handle. This should include the date, the number of the vehicle, the number of the battery, the readings of the ampere-hour meter at the start and finish, the watt meter (if such is used) reading at start and finish, the watt meter number, the ampere-hours used, the kilowatt-hours used, the number of miles driven, the road conditions, the driver, and should be ruled so as to make possible the noting of the time, voltage and amperage for seven or eight hours. The form ought to show by whom the readings were taken and have space for the noting of conditions that might be observed. With such a form the readings may be taken hourly during charging and a reasonably satisfactory record made.

Where the form is to include a number of batteries charged from a single line, and without the watt meter record, the size may be such as will be convenient, with a series of 16 spaces ruled across the sheet for entering the time, and beneath each space a similar provision for entering the voltage and amperage. This will provide for half-hourly readings for eight hours. This can be used in combination with the form first stated and this will afford a very good record of any given charge. There are other desirable records, such as that which will show the readings of individual cells at half-hour intervals, or that which will show the readings of a battery by specific gravity progressively from a voltage of 76 to 119 and from an amperage of three to 46, the reading being taken from a pilot cell.

The reader may ask why mention of forms should be made in connection with charging, and the answer is to emphasize that records are absolutely necessary and should be provided for by the owner, that there should be no possibility of error or mistake.

The charging ought to be begun as early as is practical after a battery has been in use, for then less energy is required than when a period elapses, for the reason that the acid remaining in the pores of the electrodes is in a very dilute condition and the counter electromotive force is much less than it would be if time were allowed for diffusion so that the acid would be restored to its normal condition. If the battery has been used judiciously the discharge will have been stopped at a voltage that will approximate 1.8 a

when current is supplied at the eight-hour rate, at the one-hour rate the voltage a cell may be as low as 1.68, this because there is considerable residual capacity remaining in it. At the four-hour rate 1.75 is the safe terminal voltage.

Here it is well to emphasize that the requirements of a cell as to specific gravity of electrolyte, of voltage, of amperage when charging should be carefully followed. It is not practical or even possible to apply a single rule for charging and discharging, because the cells are made to produce specific results in stated conditions, and these are usually determined from extremely careful tests. There are variables, such as temperature and age, which cannot be anticipated and which influence battery efficiency. One might assume that with increased density of electrolyte the greater would be the capacity in any case, but a maximum capacity exists that has been carefully ascertained, and to go beyond this will diminish the capacity of the cell. This characteristic is more pronounced with the negative plates than the positive.

The nearer the period of time required for charging approaches that of discharging the more satisfactory is the efficiency of the cell. The virtual efficiency increases the voltage during charging, as this must be borne in mind, and the result is a higher energy. When the charging rate is rapid, the action of the electrodes is hindered and the diffusion is not complete, the voltage of the cell is lower because of the high concentration of acid in the cells, the plates, which can cause the acid to flow freely into the solution in such a condition such as this

a higher charging rate and energy required

is as compared with the amount actually required. It is this lost energy that develops as a characteristic of all lead-acid batteries.

When a battery is charged rapidly the temperature reaches a higher temperature than would result from the internal resistance of the charging at lower rates.

In connection with battery charging there are several factors that should be considered. One of these is the rate of current, the second is the efficiency of the charging, and the third is the endurance of the cells. These are of substantial importance, and are influenced by charging. These have direct bearing on the cost of battery operation and maintenance, on the service and the mileage that can be secured.

With this, careful attention to charging means that the work that would otherwise be necessary for normal operation. That is, a battery charged properly and with regard for conditions can be expected to last to a much greater extent than can one

that is not so well cared for. The battery that is charged and discharged nearest to the rated standard will require minimum current, which is a direct cause for expense; it will give the maximum mileage, which represents the greatest service for the cost of current, and the deterioration will be insured against so far as this can be done.

When a cell is not charged for an unnecessary period following discharge the sulphation of the electrodes, which was a necessary result from discharging, is continued until charging is again begun, and when it is charged a greater number of amperes of current at a higher voltage must be passed through the cell to bring it to its maximum capacity than would be necessary than if the charging were begun immediately after discharge. The increased current necessarily means value; it means an increased expenditure without added return, and where excessive heating results the probabilities of internal discharge and consequent further loss of energy are much greater. only this, the positive plates are corroded unnecessarily and there is diminished efficiency and a loss of service, for the cell has a specific life.

The theory of charging is simple enough. With a line voltage that is not in excess of the required maximum voltage of the battery the charging connection may be made and the current permitted to flow at the amperage prescribed by the maker of the cells without any further attention. When the cells begin to liberate gas freely the amperage should be reduced to the specified rate and the gassing will diminish, and the current should be continued until there is no further increase in voltage for a period of perhaps a half hour. When this condition has been reached the voltage of the battery very closely approximates the line voltage, and were there material diminution of the line current the battery pressure would reverse the current and it would then flow from the battery through the line.

The fact that indicating instruments are used is to insure certainty and to protect against such results as might obtain from inability to judge correctly. The records provide the means of making comparisons that conditions may be determined accurately. With these a known current can be supplied, and the condition of the cells so far as voltage is concerned can be ascertained without recourse to observation, and where a considerable number of batteries are in use this is a distinct saving in time.

With reference to the instruments, the watt meter will show the precise current used, and this may be desirable as a check on current cost. The voltmeter and the ammeter are necessary that indications may be noted at any time, and with these included in the charging outfit the conditions may be known. For convenience these instruments are included in a single assemblage, these, with the necessary switches being installed on what is known as a switchboard or charging panel. The rheostat or resistance coil is sometimes included with, or it may be separate from, the panel, this being largely determined by the space that is available. For economizing space the charging panels are built to afford as many as six battery circuits, and these may be used as units to make up a switchboard of any desired proportions.

With instruments the voltage at the start of the charge can be determined, and the amperage of the current will be shown, and taking the standards established by the manufacturer the charging can be done at a rate that will insure the greatest efficiency.

What has been stated applies to batteries that have been practically discharged, for no battery should be charged unless its capacity has been reduced at least 50 per cent., or it is to remain unused for several days. Assuming that a battery has been discharged 60 per cent. and charging is to be made: When the battery is connected the voltage will be indicated on the voltmeter, provided that this is not shown by an ampere-hour meter connected with the battery in the vehicle. The approximate required voltage is known in any event. With this indication the amperage is fixed at the starting rate, which is standard for any number of cells of any given type and make, and this should be continued until the condition of free gassing obtains, which, in the instance cited, would be approximately three hours; or the current can be supplied at the starting rate for three hours, and then the amperage reduced to the finishing rate and continued for an hour and a half or two hours, or until the maximum voltage has been obtained.

In the event of the battery being discharged but 40 per cent. the same method should be followed, but the current at the starting rate will be needed for perhaps an hour and a half, and the finishing rate will be supplied until the maximum voltage is indicated. If the battery is but 20 per cent. discharged the charging can be begun at the starting rate and continued until gassing is begun, which will be within a comparatively short time, and completed at the finishing rate. But

in the estimate of the current that is needed to charge a battery 10 per cent. can be safely added to the indication needed. That is, if the current required is 80 ampere-hours, practically 88 ampere-hours, possibly 90, will be necessary, as from five to 15 per cent. more charge is needed than has been discharged from the battery.

The short periods of charging required when a battery is to be idle for a short time can be made at slow rates, and usually the slower the better, for there is less stress upon the electrodes and no purpose is served by hastening the charge. Assuming that the battery has been used intermittently during a day and the current much reduced: The period of charging can be taken as seven hours approximately. When charging is begun the record should show the time to start, the voltage and amperage, and each hour a similar record should be entered, until the battery is disconnected. Half-hourly readings will give twice the supervision and consequently a better knowledge of the time when the amperage should be reduced, for continuation of gassing means waste and the consequent deterioration.

The time for discontinuing the charge is important, for continuing a charge unnecessarily serves no useful purpose. The period the battery has been in service, the temperature and the condition of the electrolyte will have considerable influence, and for that reason no arbitrary voltage can be fixed, and maximum voltage can be best determined by two conditions—when with the reduced amperage the cells gas freely, and the voltage does not increase for a period of a half hour. While the voltage will rise steadily with the flow of the starting rate of current, when the amperage is reduced and gassing is materially decreased there will be a slight drop, and then the voltage will begin to increase until there is a second period of gas liberation and the voltage will remain stationary.

Another method of charging, which is very strongly commended by those who have had experience with it, is known as the "gravity" system, in which readings of the specific gravity of the battery are the entire record. With this the only indicator is an ammeter, which is connected in the line in the usual manner with a switch. One of the cells in a central group (never an end or outer cell) is selected as a pilot, and before charging the specific gravity reading is taken. A tabulation of specific gravities at varying voltages of the battery from minimum to maximum is made for convenient reference and this can be corrected for temperature if desired by the application of the rule of one point decrease in density for every three degrees rise in temperature, and one point increase in density for every three points drop in temperature. If the temperature of the place of charging does not vary materially so much the better. After finding the initial reading of the pilot cell, and the taking of the temperature and the correction for the condition, the battery is placed in circuit. Specific gravity readings are taken at half-hour intervals and record made. When the cell

begins to gas freely the amperage is reduced as with the other method, and the current continued at reduced rate until the cell again liberates gas and the voltage does not rise. With the gravity method of charging the condition of the battery is absolutely known and it is not influenced by any factor.

With the use of the charging plug and receptacle the connection made with the battery cannot be otherwise than correct, provided the terminal connections have not been confused, but in such an event the voltage indication would show a drop instead of an increase directly after, and in such an event the charge should be interrupted and the terminal connections reversed. With reference to battery temperature, the heating has been shown to be a material influence, and should excessive heat be indicated the charge should be stopped and the battery allowed to cool. In no instance should the temperature exceed 110 degrees Fahrenheit during charging, and in operation 100 degrees is the maximum permitted, but these points are where danger of damage is imminent and a much lower indication should be much safer.

(To Be Continued.)

CO-OPERATIVE PROMOTION.

An admirable example of co-operative promotion was brought to the attention of the people of New York City during the succession of blizzards in February, when the different companies engaged in selling electric trucks and delivery wagons in that municipality united and published a series of advertisements in the daily papers in which the results obtained from electric machines in the severe conditions were stated. The advertising was not intended to directly benefit any particular concern, but each interest was given prominence, the purpose being to bring to the attention of those engaged in transportation the possibilities with electric vehicles.

The different firms of Kansas City, Mo., have similarly united in the publication of advertising, with the intention of promoting the general use of motorized equipment and informing those engaging in transportation service, or requiring it, that "there is a truck suited to your purposes" and leaving the field open to all.

In promotion of this kind, instead of condemnation of machinery by competitors, each is constrained to speak of all other vehicles in a manner that impels confidence and will develop interest and eventual purchasing, instead of destroying it by so-called criticism and selling argument, which might prove destructive.

ADAMS PASSENGER OMNIBUS.

Seven-Seat Body with Canopy Top, Installed on Two-Ton Truck Chassis.

The Adams Bros. Company, Findlay, O., has recently produced a passenger omnibus that is intended to have all the utility of such a vehicle with the lightest and most practical body that could be used in such service. The machine is a model E two-ton chassis with a wheelbase of 160 inches, this being a special length to insure the desired stability.

On this chassis is installed a body with a substantial floor frame and floor on which is built seven seats with substantial backs and arms, each accommodating four persons, so the vehicle will carry 28 persons including the driver. The seats are spaced sufficiently so as to afford ease of movement of the passengers in entering or leaving, and seat, back and arm upholstery is substantial leather, this being well sprung to afford comfort.

At either side are running boards that are dropped between and back of the rear wheels and are practically at the height of the frame above the rear wheels, so that the three forward and the two rear seats are entered from the low running boards, and the other two from the high. The arrangement is extremely convenient.

The roof is a canopy type, being considerably wider than the seats, extending from the line of the dash back with a considerable overhang of the rear seat, and is supported on 10 steel stanchions, five at either side. This insures the fullest degree of vision for the passengers and protects them from the sun, and in the event of storm the occupants can be sheltered by ample curtains that may be dropped at the sides and ends. Handles at the sides of the seats convenience the passengers when entering or leaving the seats. The machine is driven from the left side and the control levers are located in the centre of the floorboard, as will be noted in accompanying illustration.

Adams Model E Two-Ton Truck Chassis, 160 Inches Wheelbase, Equipped with a Seven-Seat, 28-Passenger Body and Standing Canopy.

WHITE SYSTEM OF MOTOR LUBRICATION.

THE White system of motor lubrication, the invention of Ernest M. White, a consulting engineer of Globe, Ariz., who is now located in Detroit, Mich.,

Transverse Section of Motor with White Oiling System at Angle of 17 Degrees, Showing Oil in Reservoir and Crank Pits, and the Location of the Drainage Channels at the Sides.

has been recently brought to the attention of automobile motor engineers, who have manifested much interest in it. The system is a construction of the crankcase internally so as to provide for a progressive feed of the lubricant to each of the big ends of the connecting rods so that the splash flowage will be uniform in every condition in which the engine is used. As the statement would indicate, this is an application of splash lubrication.

The majority of motors in use today are lubricated by a distribution of oil internally in the engine, this method being regarded by most engineers as being satisfactorily efficient, and is applied because conditions generally establish its practicability. The ease of construction, simplicity and the certainty of operation are also factors that have impelled engineers to utilize this method, although some have adapted combinations which are regarded as productive of specific results.

Motor lubrication is dependent upon varying conditions and each moving part ought to be supplied a sufficient volume of oil to meet every requirement, this with reference to temperature, speed and quantity of lubri-

cant contained in the supply, these factors being of decided importance, for the main, crankpin, wrist-pin, camshaft and timing gear bearings, the piston and cylinder walls and the valve tappets and guides, as well as the timing gear faces and the valve cams, must be oiled.

It is evident that an excess of lubricant will not be a reason for objection unless there is an accumulation in the combustion heads of the cylinders, but a volume insufficient will quickly result in damage, and the necessity of supplying the forward portion of the motor when ascending a grade and the engine is worked the hardest has impelled the combination of a mechanical feed that will insure a supply being carried to the timing gears and forward main bearing.

The splash system is primarily the dipping of the big ends of the connecting rods into pits or gutters made transversely in the web, forming the bottom of the crankcase in which oil is collected as it drains from the walls of the case. As the motor heats the fluidity of the lubricant is increased and it flows more rapidly, but the need of the engine is greater and the distribution is faster. As the volume of oil lessens the quantity available for hard or fast work is consequently diminished, and while there might have been excess for slow operation there is not sufficient for continued use at fast speed. If the source of supply is variable with the position of the engine, with reference to the grade, mechanical feed is expected to furnish oil to those parts where the least quantity is supplied. Theoretically, the rapid revolution of the connecting rods is supposed to create a mist of oil in the crank chamber, and this should be distributed by centrifugal force. It will be understood that considerable depends

Longitudinal Section of Motor with White Oiling System at Angle of 25 Degrees, Showing Form of Crank Pits and Their Retention of Oil, the Dotted Line Indicating Bottoms of Drainage Channels.

upon the state of the fluidity of the lubricant.

The claim is made for the White system that the volume of oil splashed from the oil pits about the engine case is the same for all motor speeds, no matter whether the motor be level or placed at an inclination of 25 degrees above or below the horizontal, which is equivalent to ascending or descending a 46 per cent. grade. It will be understood that this is a gradient that is extreme, for operation in a condition that would equal this would not be regarded as practical by any experienced motor operator.

The specific value of the system is that it insures a constant supply of oil at all times, whereas in other methods of lubrication the oil is concentrated at varying places in the pits or pools and not where the fullest supply is afforded to the scoops attached to the big ends of the connecting rods. When baffle walls or separate troughs are provided the quantity in each may vary considerably, some of the cylinders being "starved" and others flooded when the grades are extreme. Operation in such conditions may result in serious damage to a motor.

The White oiling system is shown in a sketch of a longitudinal section of a crankcase and illustrates the peculiar form of the splash troughs and the "dippers" on the connecting rods, as well as the oil level in the troughs when the motor is inclined, as when climbing a gradient equivalent to 46 per cent. This indicates the possibilities in circumstances that would probably never be reached. This sketch assumes that the surface is level transversely, but the other shows a transverse section and the surface of the oil in the pits with the motor inclined 17 degrees. From these two one will gain a very clear idea of the manner in which the oil is concentrated and retained where it can always be utilized.

The oil may be contained in any convenient form of reservoir attached to the base of the crankcase, from which it may be drawn by any suitable type of pump, fed through a sight feed if desired, and then delivered, either over the timing gears or to the splash trough for the front or No. 1 cylinder. As will be noted, on the side walls of the crankcase are grooves or channels that are sufficiently inclined to insure a flow of the oil drained from the walls toward the rear of each of the oil pits or troughs, but draining into the trough behind.

Examining the second sketch one will see that the oil carried forward by the pump is drained into No. 1 trough. Here it is splashed transversely across the case and distributed centrifugally, and after lubricating this section and the working parts the drainage is collected in the side channels and carried to No. 2 trough. The operation is repeated to the last trough, and the drainage from this is into the oil reservoir. The pump is adjusted to give a stated quantity each revolution, and thus the drainage is collected progressively and an equal volume of oil supplied each trough, no matter what the number of cylinders. Each trough is abundantly provided for, and no one will receive

more than another, for the movement of the oil is specifically directed. The flow of oil from the front splash trough to the rear of the motors is illustrated, the oil being represented by what might be mistaken for wicks.

The inventor claims that besides definite efficiency the simplicity and low cost are material factors. When installed when a motor is built the cost is no greater than that of the simplest system, using a pump or the flywheel to lift the oil from the oil sump to the splash troughs. The uniform distribution of lubricants under all operating conditions is maintained to be especially desirable for practically every form of motor used for motor vehicles, motor yacht or aeronautical purposes. The inventor maintains that the system has been thoroughly tested on long and heavy grades in the mountains of Arizona, being installed in four and six-cylinder motors of different makes, and that the efficiency and uniformity of the lubrication gave marked increase of mileage to the gallon of fuel, no smoke was exhausted and the motors ran cool and had as much power at the top of a long grade as when the start was made.

CREDITORS GIVE AVERY COMPANY TIME.

The Avery Company, Peoria, Ill., which has been financially embarrassed because of lack of ready money, will continue through an arrangement by which the creditors have approved the extension of credit for a year, with the privilege of renewal of extension for a similar period if this should be necessary. The inquiry into the affairs of the company showed that it had assets of approximately \$6,000,000 and liabilities of about \$2,200,000, and there was Dec. 31, 1913, an excess of \$1,909,737 in quick assets over current liabilities. The company will issue notes to the amount of \$2,000,000, bearing interest at six per cent.

M. A. M. NEW MEMBERS.

The Motor & Accessory Manufacturers, Inc., at the last meeting of that organization admitted the following concerns to membership in the association: Michigan Steel Castings Company, Detroit, Mich., maker of steel castings; the New Haven Clock Company, New Haven, Conn., maker of motor vehicle clocks, and the Standard Tool Company, Cleveland, O., maker of lathe and hand tools.

Following the appointment of J. F. Task as special representative of the truck tire department of the Firestone Tire & Rubber Company, P. J. Talbott, manager of the Firestone branch at Dallas, Tex., was transferred to Cleveland, H. W. McFadden of Houston, Tex., was transferred to Dallas, and G. C. Falling, a sales representative in Texas, was placed in charge of the Houston branch.

ADVERTISING RATES.

Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.

Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.

Entered as second class matter, February 25, 1911, at the Post-office at Pawtucket, R. I., under the Act of March 3rd, 1879.

THE BOSTON MOTOR TRUCK SHOW.

Those who are in any way concerned in the use of highway vehicles for transportation can profitably devote one or more days to the exhibition of wagons and trucks that will be made in Boston, March 17-21 inclusive, for this will be the largest and most comprehensive display ever made in America. This statement is made advisedly, for with a realization that the attention of business men concentrated on securing machines that are in every way suited to requirements, and are ready to buy if satisfactory types can be obtained, the exhibitors have gone to extremes to display the latest and most highly perfected constructions.

While the show will include all sizes of machines, many builders have produced smaller and lighter sizes than in previous years, believing that there are large possibilities in supplying the needs of those who want faster transportation of lighter loads. That is, the demand for vehicles that have capacity of 1000 to 1500 pounds, which can take the place of the single animal wagon, will be such as to justify the production of light machines in larger numbers.

The exhibition will be attractive because of the development of the vehicles regarded as standards, to say nothing of the new types that will be shown for the first time, and there will be many chassis exhibited with special equipment developed for use in conditions where standard bodies would not be economical. The show will continue five days and during its contin-

uance a considerable number of business organizations will visit it for the purpose of investigating the possibilities with reference to special business needs. The show is expected to attract a large number of transportation experts, whose knowledge of vehicles is very essential, and who will study the type to ascertain the possibilities for differing work.

SCHOOLS FOR VEHICLE DRIVERS.

The owners of motor trucks and wagons are vitally interested in the subject of drivers, for the experience with men who have driven pleasure cars is that they believe if they operate the machine they are earning their money. With rare exceptions the best men are those who were drivers of animals, who take their added responsibilities as direct promotion, who do not become speed maniacs, who willingly work loading and unloading, who drive carefully, and who do not attempt to improve operation by making adjustments to meet their own ideas.

The human element that the owner has to deal with is usually the worst and most exasperating of any problem he has to meet. Assumedly, any man can drive a horse, but the average horse owner is decidedly better satisfied with the man who is trained to his business. The man who is willing to entrust a valuable machine to a man whom he knows little or nothing of would hardly consider a proposal to let this same man drive a valuable animal. Yet the motor equipment is condemned because it is overloaded, driven to excessive speed and "adjusted" by one who has no practical knowledge. There is no doubt that a majority of owners are directly responsible for the failure to obtain satisfactory results. Hiring men trained and recommended by the manufacturers has its advantages, but training responsible men for the exact work they are to do is decidedly better.

WHERE THE MOTOR IS ECONOMICAL.

The majority of business men owning transportation equipment can, by even casual analysis of work accomplished and conditions of service, determine where a motor vehicle can be used advantageously, and frequently the saving can be traced to other vehicles. This statement appears paradoxical, but when one understands that while the work with motor equipment may not in itself be less expensive, the time of men and other vehicles can be largely economized, the application is not in any way erroneous. Numerous instances have come to the attention of the writer recently in which the actual economy of the motorized vehicles was not in itself a large factor, but with them possibilities with other equipment was decidedly important. The thought suggested is that the adaptation of motor wagons and trucks does not necessarily mean a complete change of vehicles, but the utilization of machines where they will be advantageous.

SHOWS ECONOMY IN STREET GRADING WORK.

Analysis of Figures Submitted in Annual Report Indicate Truck Is Operating at a Saving of \$6.25 a Day---Other Late News Respecting Municipal Service Equipment.

WITH a total outlay of \$4875 for a motor truck equipped with steel body and power dumping apparatus, the street department in Montpelier, Vt., is enabled to effect a saving of \$6.75 a day, based upon the cost figures submitted to Mayor James B. Estee in the annual report, in comparison with similar work in which the state co-operated with the city.

The truck has been in service practically three months, during which time it has been employed in hauling gravel from the Winooski river, a round trip distance of approximately five miles. In its first job, which occupied one month, according to the figures of the street department, the machine effected a saving of \$384.82. However, in this computation only a partial list of the items chargeable to the truck were included, as follows: Salary of driver, \$79; gasoline, \$76.39; gravel, \$50.40; labor and team in scraping river for gravel, \$229.29; a total of \$435.08. This total was compared with the cost of a similar piece of work done with state co-operation, which was \$819.90. The detailed figures for the three months follow:

Three Months' Figures from Annual Report.

License	\$20.00
Liability insurance	49.00
Fire insurance	6.80
Driver's salary	294.00
Gasoline	205.74
Oil and grease	30.00
Repairs	87.90
Tires	90.60
Express paid on wheels to and from factory.....	40.92
Total.....	\$824.96

In connection with these figures the item of tires is explained by the fact that wider rear tires were found to be necessary, and the figure given represents the difference in cost, less allowance on the old tires. It also will be noted that the statement of cost provides for no overhead. It is assumed that the machine was stored in the city yard, and being a municipi-

pal machine it is possible that no tax allowance is considered necessary. It hardly will be denied, however, that some percentage should be included for depreciation. Assuming that this is figured at 20 per cent. the result is \$85.42 for the three months, and, making a proper allowance for the items of license and insurance, which must be considered as annual expense, the machine has been operated at a cost approximating \$13.25 a day.

How Saving Is Computed.

The teaming expense in connection with the state work to which reference has been made was \$20 a day, thus indicating a saving of \$6.75. Obviously, these figures will need readjustment in the future, since it will not again be necessary to ship wheels to the factory for fitting new tires. The item of repairs is explained by the fact that when the machine was first placed in commission, the driver met with "a little bad luck".

While detailed consideration of the figures submitted would indicate a discrepancy of \$90.90 between the saving of \$6.75 a day, and that of \$384.61 on the first job, of one month's duration, this may be accounted for in several ways. The fact that the truck was enabled to cover a greater distance in a day, may have been responsible for considerable reduction in the price of material, for instance. It is also pointed out in the report that, with a loading device at the river, much additional time could be saved, and the efficiency of the machine greatly improved.

UTILIZE ADAMS CHASSIS.

An accompanying illustration serves to offer a suggestion which may prove of decided interest to other cities. The photograph reproduced is that of an

Adams 1.5-Ton Chassis Recently Delivered to Central Fire Department of Findlay, O., and Fitted with Body by Members of the Department.

Adams 1.5-ton chassis, made by the Adams Bros. Company, Findlay, O., to which the members of the fire department in that city were able to fit their old equipment so as to give them an up-to-date piece of fire apparatus at a comparatively small outlay.

It will be noted that the chemical engine was arranged lengthwise of the body back of the driver's seat, and above the forward end of this was placed the wire basket for the chemical hose. Provision was made at either side of the wagon for carrying ladders, hand extinguishers, etc. Seats with hinged covers also permit of storing axes and other fire fighting paraphernalia.

The chassis is standard in every respect, except that of speed, being geared to run 30 miles an hour. The motor is a four-cylinder, water-cooled unit of the L head type, with bore of 4.125 inches and stroke of 5.25, this giving a rating of 27.25 horsepower under the S. A. E. formula, although it is rated by the maker at 35. Ignition is by Eisemann magneto with automatic advance. The clutch is a dry disc construction, and the selective sliding gearset affords three speeds forward and reverse. The wheelbase is 136 inches. A distinctive Adams feature lies in the use of a radiator directly in front of the dash, and a sloping hood.

HANDSOME INVALID COACH.

Accompanying illustrations present a handsome invalid coach, or ambulance, recently produced for a client of the Overland-Garford Sales Company, 6604-18 Euclid avenue, Cleveland, O., by the Willys-Overland Company in the old Gramm Motor Truck Company's plant in Lima, O. The chassis is that of the Willys Utility wagon of 1500 pounds capacity, but the body work is of special design, and since it is somewhat more elaborate than that of the ordinary ambu-

lance the term invalid coach appears to be more fitting.

The compartment shown in the smaller of the two illustrations is located back of the driver's seat, and entrance to it is by large double doors at the rear, or by a single door at the side, opposite the cot, and between the two attendants' chairs. It will be noted that the cot and chairs have been designed and constructed with an idea of providing the utmost comfort for the occupants. The other appointments include provision for running water, water cooler, wash basin, electric fan, hot air heat, medicine cabinet, stretchers, sashless drop windows, etc.

The chassis is equipped with a four-cylinder motor, with cylinders cast singly, the bore being four inches and stroke, 4.5. This gives a horsepower rating of 25.60 under the S. A. E. formula, but the maker claims it will develop 30 at normal speed. Cooling is by thermo-syphon, ignition by Remy magneto, and lubrication by a self-contained pressure feed system. The clutch is a cone, leather faced, and the selective sliding gear transmission affords three forward speeds and reverse. Brakes are external contracting on the jackshaft, operated by pedal, and internal expanding on the rear wheel drums, actuated by lever. Springs are semi-elliptic, the front members being 45 inches long by 2.25 wide, and the rear, 50 inches long by 2.5 wide. The front axle is an I beam section and the rear, a rectangular section, both utilizing Timken bearings. The standard wheelbase is 120 inches, and the tires, 36 by 3.5 inches.

KNOX CARS IN PITTSBURG.

Former Chief William Coates of the fire department in Pittsburg, Penn., declares that that city is one of the hardest in the United States for fire apparatus, because of its steep hills on which the residential sections are built. He believes that any motor driven apparatus which will withstand the hard conditions thus imposed upon them can be operated successfully anywhere.

The Pittsburg department purchased its first automobile equipment, a Knox combination wagon, made by the Knox Automobile Company, Springfield, Mass., in February, 1912. After noting its successful operation under these adverse conditions, three more were placed in service the following September. These have been followed by six more of the same type during the past few months.

The city now has 16 motor driven vehicles of all

Handsomely Appointed Invalid Coach Body, Fitted to Willys Utility Chassis, Indicating Entrance to Interior at the Side.

types, with more coming. One of these, No. 5, has been stationed at the busiest engine house in the city, and has answered 300 alarms without a single failure due to any fault of the car. In fact, it is stated that none of these 10 combination wagons, or of the five Knox-Martin tractors, which are attached to hook and ladder trucks, has failed to reach a fire, except in one or two instances where the carelessness of the driver caused a slight accident.

In connection with these machines, former Chief Coates says: "It is astonishing what these motor driven cars can withstand in the way of accidents without receiving serious injury, and our experience proves that motor driven apparatus must be of the most substantial construction to secure thorough reliability."

NEWS FROM VARIOUS CITIES.

Appropriation for Entertainment—The city council of Portland, Ore., has appropriated \$5500 for the purchase of an automobile to be used by the mayor and members of the council in escorting distinguished visitors about the city.

Apparatus Lowers Insurance Rates—Because the town of Middleboro, Mass., installed motor apparatus and a reduction of insurance rates resulted, the people of Bridgewater are seriously considering emulation of the example set by the neighboring town.

Mail Cars for Boston—Congressman Roberts has called the attention of the postmaster-general to the need for a more rapid method of conveying mails in the city of Boston. He was moved to take this action because of the success attained by the use of motor vehicles in other large cities.

Recommends Complete Motorization—Chief Fancher of the fire department in New Haven, Conn., has joined the ranks of those who favor the complete motorization of the fire fighting apparatus. In his annual report he suggests that the fire loss of \$191,540 during 1913 could have been materially reduced by the use of automobile equipment.

Advises Purchase of Tractors—After having devoted considerable time to investigating the use of tractors for hauling fire apparatus in other cities, Mayor P. L. Cofran of Topeka, Kan., has advised the adoption of motor tractors to the total exclusion of horses in the local fire department. It is probable that several of these machines will be purchased during the coming year.

Reduced Cost with Truck—David A. Hartwell, chief engineer of the sewage disposal system and superintendent of sewers in Fitchburg, Mass., states that one-half of the expense of cleaning the city's

Interior of Willlys Utility Invalid Coach, Showing Attractive Arrangement of Interior Fittings.

catch basins must be credited to teaming, and he raises the point in his annual report as to whether or not this expense could be reduced to a more reasonable basis by the use of a motor truck.

White Truck Is Economical—Commissioner Campbell of the water department in Lynn, Mass., states that the use of the new White truck, made by the White Company, Cleveland, O., and trailers, in handling 36-inch pipe in that city has effected a decided saving over horses. The truck is able to make four trips a day, as compared with two with horses. Two trailers are utilized, one being loaded at the wharf, while the other is being hauled to its destination and unloaded.

Lawrence Wants Motors—Mayor Scanlon of Lawrence, Mass., who has been opposing the purchase of an automobile patrol wagon and ambulance for the police department and one piece of motor apparatus for the fire department, on the ground that the city could not afford the money, has at last agreed that the purchase price is available. The aldermen recently submitted estimates totalling \$182,107.32 in excess of the amount necessary to run the city without increasing the tax rate, and of this amount, \$32,800 has been set aside for the motor equipment mentioned.

In the Market—The following cities are interested in the purchase of motor fire apparatus: Brattleboro, Vt., combination wagon; Knoxville, Tenn., chemical engine; Indianapolis, Ind., two pieces; Jackson, Mich., pumping engine; Scranton, Penn., tractors; Puyallup, Wash., chemical engine and hose wagon; Westboro, Mass., combination wagon; Saginaw, Mich., hook and ladder truck and combination wagon; Rock Island, Ill., combination wagon; Collingswood, N. J.; Waukegan, Ill.; Dubois, Penn.; Warren, Mass.; Toledo, O.; Chelsea, Mass.; Moline, Ill.; Utica, N. Y.; Worcester, Mass.; Port Angeles, Wash.; Dillon, Mont.; Battle Creek, Mich.; Leominster, Mass.; Bristol, Penn.; Conshohocken, Penn. (Washington Company); Merchantville, N. J.; Eastlake, Tenn.; Littleton, Col.; Omaha, Neb.; Syracuse, N. Y.; Pawtucket, R. I.; Woonsocket, R. I.; Wakefield, Mass.

FEATURES OF F. R. A. M. ELECTRIC TRUCK.

**Five-Ton Vehicle of Interesting Design Produced in De Dion-Bouton Factory, Paris, France---
Innovations Revealed at Recent British Show---Other Foreign News.**

BECAUSE of the increasing use of electric vehicles abroad, particularly by municipal authorities, etc., some consideration of the F. R. A. M. five-ton model, built in the De Dion-Bouton works, Paris, France, will prove of interest. This is especially true, since within the past few weeks the maker has invaded Great Britain with this machine, and it is not improbable that some effort will be made to introduce it in America.

Accompanying illustrations present some of the details of construction, particularly the substantial lines of the chassis. Of course, following the practise generally obtaining abroad, the bodies are built to specifications, and that shown herewith is utilized by the municipal authorities in Paris for the collection of refuse—street sweepings, etc.

It may be added that the type was first produced

The battery is of 44 cells carried in trays, six of which are located on the fore carriage directly above the motors, fully protected by a removable hood, which also provides for easy access to them whenever necessity requires. It will be understood that this fore carriage is fitted on a pivot so that it is possible to swing the road wheels in such manner that either or both sides, or ends, of the hood may be raised at will. This is still further indicated by the illustration, which shows one portion of the hood removed, and the cells exposed. The remainder of the battery, consisting of three trays, is placed under the driver's seat, where it is equally as accessible.

As to Mileage Capacity.

This battery is rated at 350 ampere-hours, with a mileage of from 25 to 30. It is stated, however, that when the vehicle is going down grade it is possible to

Five-Ton F. R. A. M. Electric Truck, Made in De Dion-Bouton Factory and Fitted with Fully Protected Dumping Body, in Service with Paris Municipal Authorities.

in the three-ton capacity, and vehicles of this weight have been in service in France for a matter of a year. The newer five-ton model is identical in design, although, of course, the construction differs, in that the components are made somewhat stronger to take care of the additional load.

Motors and Battery.

Two seven horsepower compound wound motors are suspended from the fore carriage by coil and recoil springs, each motor driving one forward wheel, independently of the other, through double reduction spur gearing to gear wheels bolted to the inside of the road wheels. This construction is brought out partially in one of the smaller illustrations, although, since the whole arrangement is suitably enclosed, it is impossible to note the details employed.

make use of the motors as braking dynamos, generating current which is returned to the battery as an extra charge. The amount of this extra charge is dependent, of course, upon the character of the locality in which the vehicle is worked.

Five forward speeds and one reverse are provided, and these are controlled by a vertical lever located at the driver's left. The average maximum speed for which the machine is geared is about 7.5 miles an hour.

Steering is by a combination of worm and bevel gear, and the vehicle, which has a wheelbase of 168 inches, has a turning circle of 33 feet. An interesting feature in this connection is that, when turning sharply, contacts automatically put more cells into circuit with one motor than the other, thereby speeding up the outer wheel.

Front View of Five-Ton F. R. A. M. Electric Truck. Showing Battery Trays Exposed for Removal—Note Enclosed Motors Driving Front Wheels.

The maker of the F. R. A. M. has taken into consideration the fact that a vehicle of this type should be available for a wide variety of service, and suitable provision has been made for fitting detachable bodies. The body shown has, as has been stated, been used in Paris for the collection and disposal of refuse. This has been designed with the idea of preventing dust and litter from being blown about the street, and the various compartments are provided with separate covers, two opening from one side and two from the other.

Provision for Dumping.

These compartments open into each other, virtually making but one, so that the vehicle is readily dumped at the rear. One of the smaller illustrations presents an attendant in the act of dumping a load, this being accomplished by means of a hand operated winch, which draws the bottom end of a steel arm on either side along a curved track, forcing the forward end of the body to a suitable angle for discharging the load. A winch is provided on each side, so that two men may expedite the work.

It should be added that the chassis is fitted with dual tires, both front and rear. The weight of the body shown is approximately two tons. Attention also may be drawn to the fact that with the provision for easy access to the battery trays, it is held to be possible to make a complete change of battery in 10 minutes. This is considered a decided advantage in municipal work, since it has frequently been the case in Paris, that a vehicle has been required to cover some 20 or 25 miles in the morning, returning to the garage at noon for a change of battery and performing a like service in the afternoon.

SOUTH AFRICAN LEGISLATION.

Inasmuch as American manufacturers of commercial motor vehicles have found a ready market for their product in the provinces making up the Union of South Africa, there will be some little interest in the new regulations which went into effect in Cape Colony, Transvaal, Natal and Orange Free State the first of the year. These provide for the registration of all

cars, and, with the exception of Natal, there is also provision for registering dealers at £10 a year. In Natal, this fee is £3.

The registration fees for cars in Cape Colony are: Weighing 1500 pounds and under, 30 shillings; 1500-2500 pounds, 40s; 2500-4000, 60s; 4000-6000, 100s; over 6000 pounds, £10. In Transvaal there is a basic charge of £2 a car, with an addition of one shilling a horsepower and two shillings for each 100 pounds weight. In Natal, the fee is £3 a car, but power is reserved to differentiate between cars according to horsepower. In Orange Free State the fee is £2 a car, irrespective of size or horsepower. With all except Orange Free State, registration is to be made annually, and in that province it is perpetual.

Restrictions as to Weight.

In addition, the Cape Colony ordinance provides that where pneumatic tires, or other tires of a soft or elastic material, are not fitted, they shall be smooth, and that where they touch the ground they shall be flat and of the following widths: Cars weighing 1500-2000 pounds, not less than 2.5 inches; 2000-4000 pounds, three inches; 4000-6000 pounds, four inches; over 6000 pounds, one-half inch for each additional 1000 pounds. In calculating the weight of a vehicle unladen, the weight of any water, fuel or batteries used for the purpose of propulsion shall not be included. Where the weight unladen exceeds 1500 pounds, such weight must be painted in one or more straight lines upon some conspicuous part of the right side, in white on black, and in letters not less than one inch in height.

In the Cape Colony a car exceeding 500 pounds in weight unladen must be fitted with reversing gear. Under the Natal ordinance, all cars exceeding 700 pounds must be so fitted. Under the Cape Colony ordinance, also, where a vehicle is being drawn by a motor car, such vehicle must have an efficient brake in good order acting on two wheels, and unless this brake can be controlled properly from the motor car, a person competent to manipulate it must be carried on the trailer. Trailers must comply with the regulations

Indicating Method of Operating Dumping Mechanism on F. R. A. M. Machine Utilized by Paris Officials.

as to cars in respect to width, tires, and also with regard to having the weight painted on the side. The Cape Colony ordinance provides that the extreme width of the car shall not exceed seven feet two inches, and the Natal ordinance, six feet six inches.

NEW FEATURES IN DESIGN.

The efforts of the British manufacturers to interest those in a position to attract sight-seeing trade in the use of so-called char-a-bancs appear to have met with decided success. Applications to operate vehicles of this character have been received from many places along the coast, the largest number being recorded from Blackpool, where the total is nearly 100.

In view of this situation, it is not surprising that several char-a-bancs were on view at the recent North of England show in Manchester, England. Most of these might be classified as of standard design, this having reference, of course, to the body work. However, the char-a-banc body fitted to the Tilling-Stevens

makers in this country. The Austin carries the plan still further, fitting the radiator directly behind the dash, where, as will be seen, it takes but about half of the space, still leaving abundant room for the steering wheel, controls, etc.

An entirely new type of mileage recorder is presented in the Thornycroft. This is a direct driven instrument, built into the gearbox, with the dial showing at the side, as indicated in the drawing. An interesting addition to the standard mechanism is the use of a winding drum centred on the main driving shaft back of the gearbox. This is brought into engagement with the shaft by means of a dog clutch operated by an easily reached handle outside the frame member.

GENERAL NEWS FROM ABROAD.

Motor Trucks in China—According to Motor Traction, a British publication: "The industrial motor is said to be making some progress with Chinese carrying firms, and a number are at work in and around Tientsin. Some of the interior posts in China have their supplies delivered by means of motor, but there is still much headway to be made. American exporting firms are said to be looking well after this trade, and it is understood that their agents are in some cases supplied with motor vehicles on 'sale or return'."

American Vehicles in India—A writer in the Contract Journal, an East Indian publication, states that a delegate from Gwalior State has been

over to America for purpose of inspecting motor agricultural machinery made there, and is bringing back with him two oil tractors, a threshing machine and other agricultural implements. He is said to consider American tractors better suited than steam tractors and plows to Indian soil and climatic conditions, besides being cheaper in price and simpler in design.

Favors Steam Wagons—It is understood that the Parliament of the Commonwealth of Australia has abolished the 20 per cent. duty on chassis imported into the states comprising that commonwealth, insofar as it applies to steam vehicles. Inasmuch as by far the larger proportion of steam vehicles manufactured are produced in Great Britain, this action would appear to be a move destined to provide a serious competition for American makers of gasoline machines, which were beginning to enjoy a good sale in the Australian states.

Innovations in Design Revealed at Recent British Show: A, Novel Placing of Radiator on Austin Machine; B, Unique Arrangement of Rear Seats on Tilling-Stevens Char-a-Banc; C, Insuring Driver's Elbow Room on Tilling-Stevens; D, Thornycroft Mechanical Hoisting Gear; E, New Gear Driven Mileage Recorder on Thornycroft Model.

gasoline-electric chassis was of particular interest because of seating arrangement, both for passengers and driver.

As will be noted by the accompanying sketches, provision has been made for entering the seats at the extreme rear without the necessity for fitting a door over the rear wheel. It is understood that space also is provided for carrying a small table in the back compartment. The arrangement of the driver's seat is with reference to insuring that the operator shall have plenty of elbow room.

One or two other innovations were brought to light at this show, as indicated by the sketches, one of which presents the new type of radiator fitted to British made Austin machines. A number of foreign makers have favored the location of the cooler behind the engine, the principal argument being that in this position there was much less danger of injury to it. This practise already has been adopted by some

CORRESPONDENCE WITH THE READER.

Installing Magneto.

Am rebuilding a pleasure vehicle for business work and, as the motor is not fitted with a magneto, desire to install one. Can you give me a few points on selecting and installing a magneto?

INFORMATION.

Weehawken, N. J., Feb. 17.

There are two general types of magneto, a true high-tension, in which no step-up or transformer coils are needed, and the low-tension, some types of which are also termed high-tension. The first named permits of starting the motor on the magneto, although some makes provide for use of dry cells or a storage battery for starting purposes.

The low-tension generally provides dual ignition, in that the motor may be operated on the magneto or cells, the latter being utilized for starting. The different types of instruments are being described and illustrated in the ignition serial now running in the MOTOR TRUCK.

It is important in selecting a magneto to ascertain how it is to be driven and the direction of drive, although some makers provide for both clockwise and anti-clockwise. The driving end of the instrument is usually marked with an arrow, denoting the direction. It is also important that the size of the motor, that is, the bore and stroke, be taken into consideration, as a large engine will require an instrument with a greater output than a small. Manufacturers of magnetos are listed in the Classified Buyers' Guide, found elsewhere in this issue, and they will supply complete data on request. In writing state bore and stroke of cylinders, number of cylinders and whether the engine is a two or four-cycle unit.

Jump Spark Ignition.

Is it necessary to have a coil with the high-tension system of ignition? Is a coil used with magnetos? Assuming that the voltage of half a dozen dry cells is six, what is it when the current jumps the gap of the plug?

C. W. B.

Cleveland, O., Feb. 27.

With the jump spark system of ignition a secondary winding is necessary to increase the electromotive force in the secondary circuit, so that it will overcome the resistance at the gap of the spark plug. Air is a non-conductor of electricity and with the space of .03125 inch between the electrodes of the plug, which is practically a break in the circuit, sufficient energy must be developed for the electricity to jump the gap.

Coils are employed with low-tension magnetos, those having but a single winding; that is, the armature. These types generate a low-tension or primary current which is built up or transformed by a separate coil. The induction coil comprises a winding of coarse (primary) wire, and another of fine (secondary) wire. This self-induction, so-called, is greatly increased by utilizing a core of soft iron wires around which the windings are placed. The same principle is employed with magnetos.

The voltage of the dry cells referred to is not sufficient to overcome the resistance of the air at the gap

of the plug. The resistance to the current increases with the pressure of the air which surrounds the points, and with the internal combustion engine the spark is employed to ignite the charge after it has been compressed by the piston, consequently considerable voltage is necessary.

The actual voltage needed is shown in an accompanying chart, the diagram depicting the electromotive force required to bridge a .02-inch gap with various compressions. At 80 pounds compression it will be noted that over 12,000 volts are necessary to overcome the resistance to which reference is made.

Assembling Light Truck.

Would you advise purchasing parts of a chassis and making them up into a light truck, one capable of carrying a ton or more? I note a number of concerns advertising rear axles, motors, transmissions, etc., at bargain prices. MERCHANT.

Binghamton, N. Y., Feb. 18.

While the writer knows of instances where trucks were assembled or built as suggested, he does not

Curve Showing Voltage Required for High-Tension Current to Bridge a .02-Inch Gap with Various Compressions.

favor it for several reasons. In the first place the commercial car effects economy because of a saving in time, and with a construction such as outlined, the breaking of a part or damage through accident may mean a considerable loss of time before the new part can be obtained. And it follows that more or less of the construction will require machine work, etc., to fit, which means a delay in the renewal of components.

The better plan is to purchase a standard make, one particularly adapted to the work, for it will be possible to obtain parts that will fit and very quickly when needed. Sometimes the cost of an assembled machine exceeds that of a standard make.

Vulcanizing Tubes, Etc.

Are the popular priced vulcanizers that use gasoline practical for repairing inner tubes and mending cuts on tires, and do they require experience to operate?

W. E. K.

Bridgeport, Conn., Feb. 26.

The vulcanizers referred to are practical. The writer knows of a number of concerns using them with success. They do not require experience as the instructions accompanying each equipment are very complete and easily followed.

THE A B C OF MOTOR TRUCK IGNITION.

Part XIX---Construction and Operation of Eisemann Magnetos, Utilizing Tapered Pole Pieces Which Are Held to Increase Intensity of the Induced Current---Single and Dual Forms---Automatic Spark Control.

By C. P. Shattuck.

ONE of the oldest and best known manufacturers of magnetos for internal combustion engines is the Eisemann Magneto Company, Brooklyn, N. Y.,

Fig. 110—Eisemann Pole Pieces.

and Stuttgart, Germany. Its product is standard equipment on commercial and pleasure vehicles both in this country and abroad, and the confidence of the company in its line is evidenced by the guarantee attached, covering it against defects in workmanship and material for a period of one year from original date of shipment.

Single and Dual Types.

With one exception the magnetos marketed by the Eisemann Magneto Company are of the true high-tension type, and this line includes both single and dual ignition water proof instruments. The single ignition system is defined as one having but one source of current supply, and obviously it is utilized both for starting and operating the motor. The dual provides two sources of current supply, usually dry cells or a storage battery, and the magneto. As previously outlined, some makers utilize the one interrupter mechanism for breaking the primary current of both sources of current supply, while others incorporate a separate or independent mechanism.

Pioneer Maker of Dual System.

The Eisemann dual system makes use of an independent battery circuit breaker, and in this connec-

tion it is interesting to note that the company claims the distinction of having devised the first dual ignition system, as early as 1903. It was termed the Eisemann-Panhard-Levassor system, and was followed a short time later by the Eisemann-Carpentier ignition.

The Eisemann-Carpentier dual system comprised a battery system independent of the magneto timer or coil. In it the battery current was commutated by a separate timer, while a double unit coil was utilized. The high-tension distributor of the magneto was utilized to deliver the secondary current of both coils. One unit of the coil was of plain form, designed for use only with the magneto; the other, a vibrator element constructed to use the battery energy. A single switch, a part of the coil, controlled both systems, and a push button on the face of the coil permitted starting of the motor on the spark.

Another early form was that employed with the model 19 Peerless pleasure vehicle. It comprised two separate and independent systems, the battery group consisting of a four-unit coil, timer, source of current and a set of spark plugs. The magneto system included the magneto, switch, transformer coil and a set of spark plugs. This arrangement involved a multiplicity of wires, quite at variance with the simplicity of the present day ignition installations.

Eisemann Type E M.

The Eisemann magneto is produced for single and multi-cylinder, two and four-cycle motors; is made in single and dual forms, and with some models the automatic spark advance or control is incorporated. As the construction of the components productive of en-

Fig. 111—Types of Eisemann Magnetos: At Left, E M, Dual; Centre, Instrument with Automatic Spark Control; at Right, E. M Single or True High-Tension—Note That Each Distributor Plate Is Provided with a Timing Indicator or Window.

Fig. 112—D C Coil Utilized with Eisemann Type E M Dual Magneto—A Key Type of Switch Is Shown at the Right.

ergy is similar, a general discussion of the type E M instrument will serve to explain how current is generated, transformed and utilized.

As with the conventional types of true high-tension magnetos, the armature of the Eisemann instruments carries a double winding, a primary and a secondary. The primary comprises windings of medium gauge copper wire and the secondary of many coils of very fine copper wire which is specially insulated, as are the layers, from each other. The shuttle armature is mounted on annular ball bearings and when rotated in the magnetic field by outside energy, a low-tension current is produced. By interrupting the primary current, a secondary or high-tension current is induced in the fine windings of the armature. The Eisemann armature is an iron core made up of many pieces of soft sheet iron riveted together, and the maker states that only the most skilled workmen are employed and the highest grade of material utilized. The inspection and tests are unusually rigid.

How Pole Pieces Differ.

The maker of the Eisemann magnetos calls special attention to the pole pieces employed. These are tapered; that is, the most extended portion thereof is approximately opposite the theoretical axis of the winding upon the armature core. It is stated that this construction results in the flow of magnetic lines of force being drawn from the extremities of the pole pieces toward the centre of the core, and that the entire volume of the magnetic lines of force are thus forced through the armature. This is said to prevent diffusion of the lines of magnetic force, resulting in increasing the volume and intensity of the induced current and the production of a hotter spark at the spark plugs. The construction of the pole pieces is shown at Fig. 110, and it is held that at no time is the armature isolated entirely from the pole pieces. This arrangement

makes use of the armature as a keeper for the magnets, preventing demagnetization. It is also stated that sudden breaking of the magnetic field is prevented, reducing wear on the couple of gears driving the magneto, and that quiet operation is assured. The imported magnets are of the conventional horseshoe type.

Make and Break Mechanism.

The make and break or interrupter mechanism, which alternately joins and suddenly separates the two ends of the primary current, follows conventional practise and consists of a bronze plate with an integral cone. It is bored to fit the armature shaft and is provided with a keyway to secure it and to insure its proper replacement in the event of its removal. The construction is locked to the armature shaft by a removable screw, and the make and break mechanism rotates with the shaft. One of the qualities of the Eisemann interrupter mechanism is the use of a lock spring to prevent loosening of the screw retaining the make and break mechanism, which may be displaced as a unit.

Operation of Mechanism.

The interrupter mechanism of the single or independent type of magneto is shown at Fig. 115, the components being lettered. The primary current generated by the magneto is led from the low-tension winding, through the armature shaft to a fixed platinum contact screw by the insulated screw retaining the bronze plate to which reference has previously been made. Pivottally mounted on the plate member is a contact lever having a fibre abutment or block. The timing lever body or housing enclosing the mechanism has two steel cams with which the fibre block makes contact, causing the lever to raise and to break contact of the platinum points. This making and breaking occurs twice during each revolution of the armature shaft, inducing a high-tension current in the secondary winding, one end of which is connected with the primary wire while the other is attached to a collector ring from which the current is taken up by a

Fig. 113—Showing Components of the Automatic Spark Control in Place and Removed from the Magneto.

Fig. 114—Eisemann Type E M Magneto, Showing Magneto and Battery Make and Break Mechanism.

carbon brush and led to the distributor brush. The distribution of the high-tension current to the spark plugs is accomplished in the conventional manner. The usual condenser and safety spark gap, the function of which has been described previously, are incorporated.

Rotation and Speed.

The Eisemann magneto is constructed to be driven clockwise and anti-clockwise, and the armature must be rotated in the direction indicated by the arrow marked on the driving end of the instrument. Four-cylinder, four-cycle motors require that the magneto be driven at crankshaft speed as two sparks occur during each revolution of the armature shaft. Six-cylinder, four-cycle magnetos are driven at 1.5 times crankshaft speed; three-cylinder at three-quarter crankshaft speed, and two-cylinder units at half crankshaft speed. Magnetos utilized with four-cylinder, two-cycle motors are driven at twice the crankshaft speed.

Wiring of E M Magnetos.

The wiring of the type E M magnetos is simple, as will be noted by referring to Fig. 117, which depicts the manner in which the primary current is short circuited or diverted from the secondary winding. The end cover of the interrupter is provided with a terminal which is connected by an insulated wire to the switch, and another lead connects the other pole of the switch to some metal part of the car, forming a ground when the switch lever is moved to the "off"

Fig. 115—Eisemann Type E M Magneto, a True High-Tension Instrument, with Distributor Plate Removed.

position. Fig. 118 shows the latest type of Eisemann kick switch, a neat, durable design.

E M Dual System.

The Eisemann high-tension dual system consists of the type E M magneto and a combined coil and switch, the former being utilized to increase the voltage of the primary current when operating on the battery. One of the qualities of the system is that the make and break mechanism of the magneto and of the battery are separate and independent constructions, an arrangement permitting of the use of the battery mechanism, for example, should the magneto interrupter become damaged, or vice versa. The distributor mechanism, however, is utilized with both battery and magneto currents because it is efficient and durable and rarely gives trouble.

The simplicity of the battery breaker mechanism is shown at Fig. 114, which illustration depicts the distributor plate displaced to show the distributor gear and its brush. The battery breaker mechanism is mounted at the back of the magneto breaker construction, and consists of a steel cam, having two projections which actuate a steel lever mounted into the

Fig. 116—Illustrating Use of Key in Timing or Setting Eisemann Magneto with Automatic Spark Control.

breaker housing. One of the features of the battery mechanism is its accessibility and ease of adjustment, the screw regulating the gap between the points being adjustable from the exterior of the housing.

Function of Coil.

The coil utilized with the dual system is shown at Fig. 112. It is of the non-vibrating type and combines a switch with a starting mechanism, also a push button which, when depressed, with the lever on the battery side, is productive of a single spark in the cylinder of the motor. The D R C type of coil has a ratchet arrangement which results in a series of sparks. Both designs are mounted in a compact case which is fitted to the dash, but the coil and switch rotate within the housing. One of the qualities of the design is that it may be dismantled readily and the coil core displaced.

The wiring plan of the system is shown at Fig. 119. The high-tension current is led from the collecting ring of the magneto at H M to a similarly marked terminal on the coil, thence to the switch member H on the coil, and to H on the magneto. The last named terminal is in connection with the distributor arm and

brush. Distribution is in the usual manner.

When the switch lever is moved to the "Battery" position, the primary current of the magneto (M A, Fig. 119) is grounded. The battery current flows into the coil at +, through the coil and thence to R on the coil to R on the magneto, where it is interrupted. From the battery breaker the current returns to the battery through the ground. With the motor inoperative, the interrupter is inactive, necessitating the use of the starting push button to which reference has previously been made. Placing the switch lever in the "Off" position, when operating on the battery, cuts off the current from the coil, and the magneto current is also short circuited. Moving the lever quickly from the battery to the magneto position results in the magneto supplying current for ignition.

Automatic Spark Control.

With magnetos equipped with variable advance—that is, having interrupter mechanism that may be manually operated to cause the break of the primary current to occur earlier or later—the operator or driver depends upon his judgment as to the proper advance.

Fig. 117—Wiring Plan of Type E M Single Eiseemann Magneto—The Fine Lines Indicate Primary Leads and Connections.

It has been pointed out in previous discussions that the greatest efficiency or hottest spark is obtained when the greatest number of lines of force are cut, or in other words, when the armature is in a certain relation to the pole shoes. It is at an exact point that the break of the contact points should occur. If the spark occurs too late, the motor will not develop its maximum efficiency, and if too early, its mechanism is likely to be subjected to undesirable stresses.

These faults are held to be overcome in the Eiseemann magneto fitted with the automatic spark control shown at Figs. 111 and 113. Among the advantages of the construction emphasized are: The elimination of the spark lever and linkage, increased flexibility and 60 degrees advance, economy of fuel, easy starting, automatic retard of the spark when starting, and a uniform, intense spark at all motor speeds.

Construction of Control.

The components of the automatic spark control are shown at Fig. 113. The magneto is of the same construction, as the standard high-tension instrument just described, with the addition of the automatic mechanism. The advance is obtained by the action of centri-

fugal force on a pair of weights attached at one end to a sleeve through which runs the shaft of the magneto and hinged at the other end of the armature. Along the armature shaft run two helicoidal ridges which engage with similarly shaped splines on the sleeve.

Fig. 118—Eiseemann Kick Type of Switch.

When the armature is rotated, the weights move outward, exerting a longitudinal pull on the sleeve, which in turn changes the position of the armature with reference to the pole pieces. In this way the moment of greatest induction is advanced or retarded and with it the break in the primary circuit, for the segments or cams which left the circuit breaker and cause the break of the primary circuit are fixed in the correct position, and thus it is held that the interruption of the primary current occurs only at the moment when the greatest number of lines of force are cut.

To apply the automatic control principle to any motor, there have been produced advance spindles of varying pitches, obtaining 19, 25, 38, 45 and 60 degrees advance. For use in connection with these spindles there are 16 different springs, and the company states that with these parts, in connection with the governor mechanism, 160 advance curves may be obtained, and by varying the length of the stop on the bronze nut, many more are possible.

Novel Timing Device.

One of the qualities of the construction is the simplicity of the timing of the instrument. At the back of the automatic regulator case is cut a slot. By inserting a special key the armature is held in the proper position for connecting it to the driving member. This eliminates noting the position of the armature or break of the contact points, and a further advantage

Fig. 119—Wiring Plan of Eiseemann Type E M Magneto Providing Dual Ignition.

is that the key prevents movement of the armature, simplifying the setting of the instrument.

The arrangement is shown at Fig. 116, A being the pin of the key which catches in one of the holes of the rectangle. It is essential in the timing operation that the point B and the edge of the regulator case correspond.

Care and Maintenance.

The Eisemann Magneto Company recommends that the break or gap of the magneto contact points of its instruments be .015625 inch and those of the battery slightly more. With the dual system, six-volt storage batteries, or 10 dry cells connected in multiple series, are used. In the matter of wires, it is stated that the high-tension cables should be .3125 inch in diameter and those of the primary .21875 inch. The gap of the spark plugs should be the same as the magneto contact points, .015625 inch. The parts requiring lubrication are marked "Oil", and a few drops of high grade lubricant should be used every 1000

licensees under these patents, which are designated as follows:

Hunter	670,405	March 19, 1901
Hunter	696,143	March 25, 1902
Hunter	625,953	May 30, 1899
Thayer	678,063	July 9, 1901
Martin	1,018,248	Feb. 20, 1912
Hight	693,836	April 29, 1902
Liebau	655,724	Aug. 14, 1900

In addition to the above, applications for patents for improvement of the devices and combinations stated above are now pending. The statement is made that the owner of the patents and the licensees will avail themselves of every protection afforded by law to prevent invasion of their rights, and that this is intended to be of general information to the trade.

Included with this are diagrams representing the combination of a motor truck with a trailing wagon supported on wheels at the rear and supported on the truck at the front by means that will admit of a rocking motion, and a combination providing for a more resilient support for the frame carrying the motive

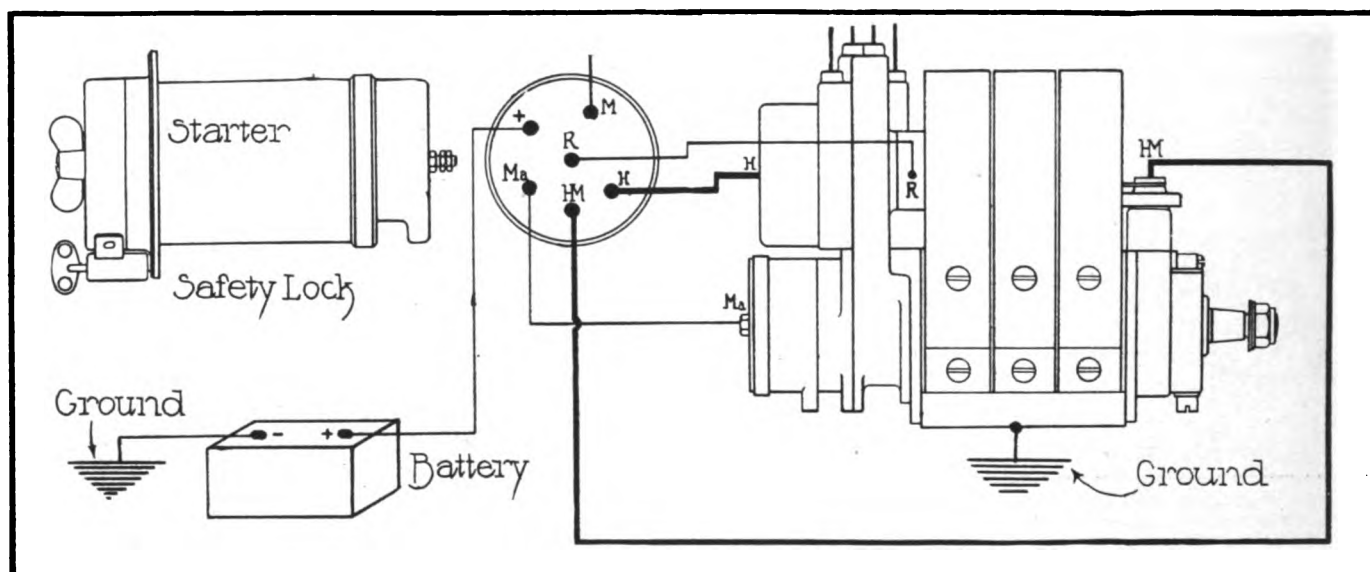

Fig. 120—Wiring Diagram Utilized with Coll D 2 U—The Heavy Lines Indicate Secondary Wires; the Light, Primary.

miles of service. Lubricant should be used sparingly, as flooding the parts will breed trouble.

(To Be Continued.)

Ed. Note—The next installment will deal with the various types of instruments manufactured by the Simms Magneto Company.

MARTIN TRACTOR PATENTS.

The Martin Tractor Company, Springfield, Mass., has caused information to be sent generally to motor vehicle manufacturers, dealers and users, that no combination of any automobile with a wagon in such a manner that the wagon is supported on wheels at the rear and in front on the back of the automobile by any rocking connection whatever, can be made without infringing upon the basic patents owned by C. H. Martin. The Martin Tractor Company and the Knox Automobile Company, Springfield, Mass., are the only

machinery than for the wagon carrying the load. With the Martin tractor the forward end of the wagon carrying the load is supported on a turntable so pivoted that the elevation or lowering of the rear wheels above or below the plane of the tractor frame will not cause stresses upon the tractor.

The management of the Universal Motor Truck Company, Detroit, Mich., is now directed by George Uihlein of Milwaukee, who has established headquarters at Detroit. F. K. Parke, formerly vice president and general manager, and G. L. Brush, formerly assistant secretary, have retired from all association with the company.

The address of the executive secretary of the Electric Vehicle Association of America is now 29 West 39th street, New York City, where all communications not intended to reach the business office of an official of the association should be addressed.

HINTS FOR PROPER MAINTENANCE.

IN THE absence of a grinding machine some workmen complete repairs by boring and turning, when a fine degree of accuracy would be advisable.

Fig. 1—Novel Use of Copper Tubing in Intake Manifold.

Many repairmen do not care to go to the expense of installing grinding machines, although desiring their use. At Fig. 2 is presented a grinding attachment, the designer of which states may be attached to any engine lathe of sufficient centre capacity.

The grinder itself is carried by a slab and stud-shaft, the arm of which is about 1.75 inches in diameter, so as to insure the necessary rigidity. The slab is attached to the face plate of the lathe by means of two .75-inch bolts, of which the top one is arranged in a radial slot, to facilitate adjustment of the work in hand. Upon the arm of the studshaft is mounted a length of solid drawn hydraulic tubing, which revolves on two brass bushings forced and sweated into the ends of it, thus leaving an annular space for the lubricant.

The tube carries a driving pulley on its inner end, the grinding stone being attached to the outer end. The driving pulley is secured to the tube by means of two set screws. This pulley is fitted with a sufficiently convex face, in order to eliminate lateral slip of the belt. The outer end of the tube is threaded to receive a thimble, which is screwed and sweated into place.

Owing to the concentric path which the grindstone spindle follows, the use of a floating countershaft is necessary. The connecting rod to the latter is shown broken off in the lower illustration, and the arrangement of the floating countershaft is depicted in the upper drawing. As previously mentioned the feed of the grinding stone is adjusted by the bolt situated in the radial slot, while the travel is supplied by the lathe slide rest.

NOVEL USE OF HEAT.

A novel use of the hot water of the cooling system is shown at Fig. 1, it consisting of utilizing a coil of copper tubing inside the intake manifold of the motor. As will be noted, one end of the tubing is tapped into the water jacket of the last cylinder and the other end to the pump, thereby forming a hot water circuit from the jacket, through the coil, and back to the pump.

The copper tubing is bent to form a helix, and with annealed pipe it is an easy matter to obtain the required spiral on an ordinary broom handle.

Two half-inch holes are drilled in the intake manifold, through which the coil of tubing is threaded. The openings are closed by two small brass bushings, these also serving to retain the tubing in place. Leakage of air is eliminated by sweating the tubing to the bushings. By the use of an ordinary pipe union at each end of the coil, the tubes leading to the water jacket and pump are attached as shown in the illustration. It is stated that there are two advantages to be derived from the device. First, the incoming mixture is given a swirling motion, thereby breaking up any particles of fuel not vaporized by the carburetors; second, the heat prevents the possibility of condensation of the fuel and also makes for a more homogeneous mixture.

HARDENING SMALL DRILLS.

Hardening and tempering small taps and drills requires considerable care and experience if perfect work be obtained. When undertaking the work the taps and drills are held with the spiral or thread immersed in lead which has been brought to the melting point in an iron or earthenware crucible. Pieces of very small diameter should be left in the molten metal for about 60 seconds. They should then be withdrawn and plunged in cold water. If the bath be of the correct temperature no lead will adhere to the work when they are removed.

After chilling the tools should be cleaned and tempered. The most convenient way is to lay them on a sheet of old iron held over a charcoal and gas fire. The tray should be rocked a little during the process in order that the pieces may be heated uniformly. When they attain a dark straw or gold color they should be

Fig. 2—Grinding Attachment for the Lathe.

again plunged in water. It is held that by the above treatment the degree of heat is strictly limited, and it is impossible to burn the edges as with an open fire.

MACHINERY, TOOLS, EQUIPMENT AND SUPPLIES.

A COMBINATION welding and decarbonizing outfit is being marketed by the Cox Brass Manufacturing Company, Albany, N. Y. It provides means

Case Containing Tips, Valves, Etc., Utilized with Cox Combination Welding and Decarbonizing Outfit.

for removing carbon from the cylinders of the motor by the use of the oxygen process and for welding broken parts. It has several advantages, perhaps the most prominent of which is the saving of time. Ordinarily the work is sent outside, which generally results in delays, and, in addition, the profit accruing to the garage, repairman, etc., is very small, this usually being a percentage.

With the Cox outfit the welding work may be performed quickly by the repairman, and the company states that the operation of the equipment can be learned in a very short time by the average mechanic. One of the qualities of the apparatus emphasized is that it will do the work thoroughly, welding broken parts made of brass, steel, iron, bronze, copper and aluminum. With the equipment it is obvious that many repairs formerly requiring considerable time with old methods can be made quickly.

The process of welding is well known. The principle of the method is the use of a small concentrated flame of a temperature approximating 3600 degrees Fahrenheit, applied directly to the metals to be welded.

The Cox dual equipment comprises a highly polished oak case, nickel trimmed, with cover and handle as shown in the accompanying illustration. The case contains a welding torch with six interchangeable tips, sufficient to perform welding on all kinds of work; one oxygen reducing and regulating valve, with gauge and shut-off; one acetylene reducing valve, with gauge and shut-off, fitted with special coupling for attaching to Prest-O-Lite gas tank; 12 feet of acetylene hose, 12 feet of oxygen hose and a complete assortment of welding rods for welding copper, brass, iron, bronze, steel and aluminum. The wrenches, goggles, etc., are packed in a special, convenient case.

In addition there is included a decarbonizing torch

and swab for removing carbon from motor cylinders by the oxygen process. The last named provides the dual equipment to which reference is made above.

The Cox Brass Manufacturing Company calls especial attention to the low cost of the apparatus, which is marketed as a unit or separately. A special gauge for showing the supply of oxygen on hand is listed at a slight extra cost. The company supplies complete instructions for the use of both systems, and maintains a free service department for the benefit of its customers. One of the features of the department is the expert information supplied for repairs out of the ordinary.

The company calls especial attention to the regulator or reducing valves, stating that they are so constructed as to automatically reduce the pressure of the oxygen from that of the tank of 1800 pounds, and that of the acetylene tank from a pressure of 200 pounds, to a low, workable pressure of from zero to 25 pounds. The pressure is regulated to an even consistency and does not vary from a set amount. Complete details and price lists will be forwarded upon application to the company.

COCHRAN PIPE WRENCH.

The Cochran Pipe Wrench Manufacturing Company, 78th street and Woodlawn avenue, Chicago, is marketing the Cochran pipe wrench shown in an accompanying illustration. It is warranted to give 50 per cent. more service than conventional designs, and the guarantee is very liberal. One of the qualities of the tool emphasized is that the compression strain is exerted on that part of the member which is the strongest.

The frame and handle are one solid piece, and a rocker replaces the usual pin, eliminating opportunity of shearing stresses. The jaw is of the hook type and is with the inserted jaw, drop forged from the best grade of tool steel. The rocker and adjusting nut are also constructed of high grade material.

Cochran Pipe Wrench, Having a Solid Frame and Movable Hook Jaw.

The maker claims a perfect grip and release by its construction, and states that the tool cannot be injured by a side pull, owing to its solid frame construction. It is guaranteed not to crush or lock on pipe.

STEWART AUTO THERMO-METER.

The Stewart-Warner Speedometer Corporation, Chicago, has brought out a thermostatic temperature indicator, termed the Stewart Auto Thermo-Meter, which is attached to the filler cap of the radiator and registers, by means of a hand passing over a calibrated dial, the temperature of the water cooling system.

Stewart Auto Thermo-Meter.

One of the qualities of the design emphasized is that a thermostat is utilized and its bar is affected by the temperature of the air over the water. The heat or cold so actuates this bar that it moves a pointer over a calibrated, glass covered dial. The last named provides for readings from 30 to 212 degrees Fahrenheit, and it is stated that the figures may be read easily. It is also claimed that, owing to the pointer hand moving over a curved dial, it is a simple matter to determine its position even when it is so dark that the Thermo-Meter can hardly be distinguished.

The function of the device is to enable the operator to note at a glance the operating conditions of the motor, as it is obvious that with too high a degree of temperature the indicating hand will warn the driver of trouble. Similarly, upon the cooling fluid attaining a temperature in the neighborhood of 32 degrees, the hand will indicate the need of attention to prevent freezing. The Stewart Auto Thermo-Meter is finished in brass or nickel and is moderately priced.

MOORE CHAIN HOIST.

The Chisholm & Moore Manufacturing Company, Cleveland, O., maker of chain hoists and trolleys, is marketing the Moore anti-friction chain hoist, produced in capacities from one-half to 10 tons and is provided with an improved automatic brake which locks the load at all points and yet permits of a very free and smooth lowering movement.

The brake is adjustable, permitting of lowering the load more freely, and all friction surfaces require no oiling as they are self-lubricating. The locking device is released by a slight reverse pull on the hand chain. The maker states that it has less working parts than any other hoist except the direct differential, and that spur gears are utilized.

The chains are made of the highest grade material and are tested and stretched to gauge on a pull of 100 per cent. greater than the maximum load they are intended to carry. The height of lift varies from eight feet for the half-ton hoist to 12 feet for the 10-ton equipment. By utilizing two extra feet of both main

and hand chain, an additional foot may be obtained. The company will forward catalogues and price list free on request.

UNIVERSAL HACKSAW MACHINE.

Power hacksaws are time savers in the repair shop and service station, as not only is considerable time wasted in cutting metal by the hand tool, but with large pieces it is not always easy to make an accurate cut. The West Haven Manufacturing Company, West Haven, Conn., with postoffice address, New Haven, produces a line of hacksaw frames and blades, and is marketing the Universal hacksaw machine shown in an accompanying illustration. It has a capacity of six-inch solids, and one of the qualities of the equipment is the quick return of the stroke, this being 3:1. The blade also lifts entirely from the work on the return stroke.

The machine is designed especially for economy and speed. There are two fixed strokes, a five and a seven-inch, and only one adjustment is required; that is, for work above five inches in diameter or square. The maker states that the adjustment may be made in the short time of 15 seconds. Another feature of the machine is that the automatic lift is adjustable for wear. It is stated that the automatic stop is absolute, and that the pulley can be lubricated without throwing off the belt. The company calls special attention to the shafts of the machine, stating that these are silent, and being on the bed of the machine make for maximum service. All parts are interchangeable.

The size of the pulley employed is six by 1.75 inches and the speed is 240 revolutions a minute. The length of the saw blades is 12 and 14 inches. The floor space required is 52 by 16 inches; height of work vise, 28 inches, and height over all, 42 inches. The net weight is 240 pounds; gross, 300. All castings are

Universal Hacksaw Machine, Having Rapid Return of Stroke and Being Capable of Cutting Solids up to Six Inches in Diameter.

numbered, making for convenience when ordering spare parts. The company issues a catalogue of its products, which will be mailed free on request.

New Commercial Car Accessories

Kellogg Starter.

A compressed air type of motor starter for model T Ford cars is being marketed by the Kellogg Manufacturing

Company, Rochester, N. Y., maker of power tire pumps, etc. The system comprises in combination a pump and starting mechanism, storage tank, starter button and pump control. It is stated that the outfit is installed with no other work than the attaching of a bracket at the front of the machine and that it does not detract from the appearance of the car.

The unit comprises a cylinder, the piston of which is actuated by air entering from the tank at high speeds. A chain connected with the piston operates a drum in the housing mounted at the front end of the vehicle. This chain makes one complete turn around the drum. The fan belt pulley is replaced with a combination pulley, sprocket for driving the pump and a clutch which automatically engages with the motor when the starter is operated. The application of air is gradual, but the power developed during the balance of the piston travel is such as to spin the motor. A spring returns the drum, preparing it for a second application of energy. It is automatically performed.

All working parts are fully enclosed, and provision is made for inflating tires. Control of the pump for storing compressed air is by a button, and a similar member operates the starter. Several starts are held to be possible with one charging of the tank.

Stanweld Wire Wheel.

The Standard Welding Company, Cleveland, O., is manufacturing a design of wire wheels for attachment to the model T Ford car, and one of the qualities of the design is that it may be applied to both the front and rear by utilizing the old wooden wheel flange and bolts. The hub of the Stanweld is a steel stamping; the spokes are reinforced at both ends, and the three-cross method of lacing is employed.

The finish is two coats of black enamel baked on. Among the features emphasized in the wheels is lightness.

They come complete for attachment, and their application does not involve any other work than removing the old flange and bolts, and displacing the wooden wheel. Special tools are not required.

Auto Signalite.

The Auto Signalite Company, 735 Seventh avenue, New York City, is marketing the Auto Signalite, which differs from the usual signalling devices in that a small lever is employed to operate it. This lever is actuated by the driver, slightly in anticipation of stopping, turning to the right or left, or continuing in the original direction.

Combined with the signal is a tail light and number plate bracket, these being compactly arranged in a cylinder having dimensions of 5.5 by 12.5 inches. Ease of installation is emphasized by the maker. The device can be attached

to any part of the rear of the vehicle. An electric light illuminates the words "Stop", "Right", "Left" and the red light.

Duplex Piston Ring.

M. L. Dunham, 140 West 52nd street, New York City, is manufacturing the Duplex piston ring. The maker states that when fitted to a piston the gas cannot pass the rings; that smoking is eliminated, and that the efficiency of the motor is improved. One of the qualities claimed for the Duplex is that wear does not affect the joints. It is also stated that it remains sealed at all times.

It is claimed that the tension of the

ring is balanced or even, and that its gas tight feature is obtained with a very light pressure. When in service the ring has an outward tension, also a double spiral tension; that is, the free ends not only exert a force outwardly, but expand radially in opposite directions around the cylinder wall, and will fit themselves to a worn or a new cylinder.

Ed. Note—The editor of this department invites manufacturers, distributors and agents to forward illustrations and descriptive matter of commercial vehicle accessories and equipment. The name of maker, city and street address should accompany all data. Photographs are preferable to drawings. Address all communications to this department of Motor Truck.

Ray Socket Wrench.

The Ray socket wrench is manufactured by the Packer Auto Specialty

Company, Chicago, for which Ralph Walcott, 1790 Broadway, New York City, is distributor. The maker states that the wrench will fit every nut and bolt on a car, and may be utilized in places difficult of access with the conventional tool. The wrench proper is sturdily constructed and when utilized with the universal joint provided with each outfit, it is claimed that work may be accomplished at any angle up to 90 degrees.

The complete equipment includes, in addition to the wrench, which is nickel-plated and highly polished, a long extension bar, two short extension bars, one large and one small screw driver bit, one universal joint, one four-inch spark plug socket and 30 case hardened cold drawn steel sockets. These are graduated in sizes and fully guaranteed. This equipment comes in a wooden case, and the maker states that it will perform a variety of work as well as eliminate the necessity of carrying a large number of conventional tools. The company also manufactures a small set which differs from the larger member in that 11 sockets are provided in addition to the spark plug member. The smaller outfit comes either in a leather case or an oak box.

Spark-No Lock.

The H. W. Johns-Manville Company, New York City, is marketing the Spark-No lock, an ingenious device for locking the ignition of the car and preventing use of the machine by others than those intended. It is attached to the dash, and the hands are moved over a calibrated dial by means of two little knobs. These are employed for starting and operating. One of the qualities of the device is that it is impossible for anyone riding with the driver to discover the starting combination.

If anyone attempts to steal the machine, not only is the ignition cut off, but an alarm is sounded by a bell. The signal is also sounded if one tampers with the lock. The action of the device is similar to a combination lock, but differs in that the combination operates a switch, and this switch cannot be closed unless hands are properly set on dial. Spark-No Lock is moderately priced.

STANDARD BUILDERS OF GASOLINE TRUCKS.

Service Vehicles Produced for 1914, Giving the Name, the Manufacturer, the Location of the Principal Factory and Executive Office, and the Different Sizes of Machines Built in Capacities of Tons--A Complete Directory of the Industry of the United States.

PLANT OFFERED TO MARSHALL.

The Board of Commerce of Marshall, Mich., and business men of that city are considering the proposal made them by Murray Irwin, sales manager of the Lewis Spring & Axle Company, Jackson, Mich., which, if accepted, will result in the establishment of a plant at Marshall to construct the Irwin wagon, which is now produced by the company he represents. The facilities at Jackson are limited and as the purpose is to construct the machine in considerable numbers, a separate factory is desired. The machine is 1500 pounds capacity and is sold for a moderate price. The Marshall interests are asked to subscribe half of the capital stock of \$65,000, and of this \$10,000 is to be devoted to the payment of patents, designs, materials, etc.

WILL BUILD MILLER WAGONS.

The Kosmath Company, manufacturers' representative, 707 Ford building, Detroit, Mich., which markets the Kosmath delivery wagon, has made announcement that it has purchased from the receiver of the Miller Car Company the designs and material which that concern had on hand when it failed. The Miller company was building a 1000-pound delivery wagon. The Kosmath Company has transferred the designs and material to its factory in Detroit, where it purposes to continue the manufacture of these machines.

The annual meeting of the stockholders of the United States Rubber Company will take place March 17 at New Brunswick, N. J., at which time the annual reports will be made and officers elected.

SPECIFICATIONS OF 1914 MOTOR TRUCKS.

The Principal Dimensions and the Important Details of Construction and Mechanical Equipment of 312 Different Sizes or Types of Service Wagons Produced by 137 of the Leading Manufacturers of the American Industry.

THE motor service vehicle industry is, as is any other industrial classification, constantly in transition. By this is meant that new enterprises are being promoted and developed, others are in the course of liquidation, some are especially active and others are for the time being dormant, so that there is at all times a rather uncertain standard if one were to judge by numbers. If one were to make comparison and determine the progression or retrogression by the count of those firms that may be rated as productive, there would undoubtedly be wide variance from actual facts.

There are assumed to be approximately 250 firms representing the entire industry, but of these a large proportion cannot be regarded as productive. Many of them have been merely projected, others have perhaps built a single vehicle, and still others have engaged in manufacturing in a limited way and market their productions in a small area, in some instances doing business direct from the factory to the customers.

A list of those doing business as builders of service vehicles will indicate that the industry is very generally distributed throughout the country, and that there

has been decided increase in manufacture of motor trucks in the Western and Pacific Coast states.

Specifications as offered to the people have a definite and useful purpose, for they afford accurate knowledge of differing dimensions that are of material importance to those considering purchasing. These specifications are generally prepared to meet the convenience of the individual compiling them, and if there is any criticism to be made of the average catalogue presentation it is from the fact that it will not contain all of the detail that may be useful. That is, the manufacturers have never united upon any uniform manner of informing the people of the engineering data of what they have to sell.

There are undoubtedly good reasons for variance of opinion as to literature for publicity and promotive purposes, but the value of uniformity can be best understood by those who make comparison of two catalogues with a view of learning the main details of construction. Information of real worth is neglected and that which is inconsequential is exploited, a statement that can be substantiated in a general way.

The chief value of specifications is in uniformity of

Specifications of Three Hundred and Twelve Gaso

Auto, automatic; Gov, governed; Opt, optional. Motor Lubrication: Spl-pres, splash and pressure. Clutch: Exp bd, expanding band; Con bd, contracting band.

presentation, that there will be the largest measure of information compatible with the opportunity for publicity, and in this connection it is well to emphasize that no matter how presented the specifications of a given type of machine are the same data, the main variance being in the manner of compilation. That is, the dimensions and proportions will not vary because of differing statements relative to them, and for this reason a given tabulation that contains the main facts will have practically the same information that will be found in any other, although the arrangement of the two will be entirely different.

As a matter of fact arrangement is a matter of personal opinion with the person making the compilation, and aside from an individual view to systematic presentation or convenience in reading one may be said to be equal to any other that contains similar information. There is, however, a decided advantage in the form of tabulation that will permit the greatest volume of information in a given space. The specification table that would contain every fact worthy of consideration by the engineer would necessarily be far more complete and comprehensive than that which would meet the ordinary requirements of those seeking general data. For this reason, as well as from lack of space primarily, it is impossible to give more than a few of the principal facts concerning a large number of machines.

The following tabulation, which is reproduced by the MOTOR TRUCK through the courtesy of the Commercial Vehicle, New York City, can be commended to the reader for its completeness and the

thoroughness of compilation. Practically every detail has been supplied, and the table from the aspect of the most critical is comprehensive, for all important data are presented uniformly, making possible an extremely wide range of accurate comparison. It shows 32 essential facts of the mechanical construction of practically every one of the 312 different types of American machines included in it, and in addition gives the completed chassis price of each.

Considering the value of this table further, it will be noted that it contains the names of 137 different makes of vehicles, giving all the models or types marketed by the names stated, and the number produced by any one maker ranges from one to seven, and it is interesting to observe that of the makes tabulated 59 builders produce one model, 35 build two, 20 build three, seven build four, 10 build five, four build six and two build seven. The capacities range from 400 to 14,000 pounds. It will be noted from the list that precedes this statement that a considerable number regarded as manufacturers are not included in these specifications. This fact prompts the comment that the firms whose machines are named in the following tables may be regarded as active and more or less factors in the industry.

The magnitude of the individual firms and the volume of their business is not represented by the specifications, but the tabulation includes practically every concern of importance in the industry. The reader can refer to any make of vehicle by the trade names, which are arranged alphabetically, and in the order of load capacity where more than one size is built.

ABBREVIATIONS:—Gearset: Sel, selective; Prog, progressive; Plan, planetary; Fric, friction; Ind C, individual clutch. Gearset Location: Amid, amidships; Unit M, unit with the motor; Unit J, unit with the jackshaft; Unit X, unit with the rear axle. Final Drive: Int G, internal gear; Bevel, shaft with bevel; T Worm, shaft with top worm; Chain, by chain to the rear wheels. Springs: Ell, semi-elliptic; Ell, elliptic; Ell, elliptic; Plat, platform. Bearings: Roll, roller; B & R, ball and roller; Opt, optional.

Typical Models of American Motor Wagons and

Trucks That Are Standards for 1914 Production.

Specifications of Three Hundred and Twelve Gaso

PARK BUYS MOSLER FACTORY.

The purchase of one of the most modern and best equipped factories of the kind in America by a park system, with the intention of eventual demolition, was the decidedly unusual transaction by which the plant of A. R. Mosler & Co., Mount Vernon, N. Y., passed into the hands of the Bronx Parkway Commission, which purposes to utilize the site in carrying out its plans to beautify the section of New York City of which it has control. The price paid for the property is said to be \$93,000. Mr. Mosler will have six months to establish his business elsewhere, and the statement is made that when it takes place the business will be organized with a department for producing spark plugs and another for the manufacture of screw machines, which he specializes.

U. S. TIRE SALES LARGE.

In the annual report of President Samuel P. Colt of the United States Rubber Company, which covers a period of nine months for all the subsidiary companies, and for 12 months for several of the concerns, the statement is made that while 1913 was a year of falling prices the volume of business transacted during the last nine months of 1913 was larger than for the corresponding period of 1912, although a given quantity of manufactured stock would necessarily represent less because of the difference in the market value. The sales of tires by the United States Tire Company showed a substantial increase, and considering the variance in demand for some of the other products, from weather and other conditions, this was very gratifying.

The net profit of the company for the nine months was \$9,677,532.81, and the surplus earnings, after paying dividends, was \$1,046,611.58, and at the end of the year the company had on hand approximately \$10,000,000 in cash. The surplus carried as a liability in the statement is \$19,129,504, of which \$350,156 pertains to minority stock interests. The net sales for the year reached the total of \$87,349,692. The report is regarded as very satisfactory and encouraging.

STANDARD TYPES OF 1914 MO

Index of Illustrations Which Show One Representative line and Electric

The makes are arranged alphabetically, and referring to the index this pre designation of the body equipment illustrated, the number of the illustration

HOOD SUCCEEDS WILCOX.

The Standard Motor Truck Company, Detroit, Mich., has named Wallace C. Hood as sales manager to succeed George D. Wilcox. Mr. Hood was formerly sales manager for the Chalmers Motor Company and the Empire Automobile Company, and is widely known in the automobile industry, though he has been identified with the marketing of pleasure vehicles the greater part of the time.

CONTRACTOR BUYS TRUCKS.

The Holbrook, Cabot & Rollins Company, Springfield, Mass., which has the contract to build the Dwight street underpass, an important railroad construction that will shortly be begun, has purchased two Pierce-Arrow five-ton trucks, equipped with hydraulic hoists and dumping bodies, which will be used in this work. The delivery is to be made as quickly as possible.

COMMERCE AGENTS DINED.

The Commerce Motor Car Company of Illinois, the concern that markets the Commerce 1000-pound delivery wagon in the State of Illinois, with headquarters in Chicago and with representatives in the principal cities and towns, recently entertained its agents at dinner at the Sherman house, Chicago, there being a large number of the dealers and salesmen present. Among the guests were several of the officials of the Commerce Motor Car Company from Detroit, and chief among them were those having to do with the marketing of the machines. The social feature of the event was of importance, but the principal purpose of the gathering was to promote the spirit of co-operation and to discuss plans for the very active campaign which has been inaugurated. The enthusiasm created was of a character that was very satisfactory and will undoubtedly be productive of excellent results.

The New England Telephone & Telegraph Company has purchased a two-ton Pierce-Arrow truck for use at its Springfield, Mass., headquarters.

CHASSIS AND BODY EQUIPMENT DATA.

The Types of Bodies Supplied as Stock by Manufacturers Designated by Models, and the Available Loading Space of Each, with Factory Prices.

NO DETAIL of motor vehicle construction is of greater importance to the man seeking information than the dimensions of the space in which freight can be carried. The inquirer is justified in believing that the engineer designed a given chassis to carry a specified maximum load in all working conditions, and that with a standard type of body the weight will be so distributed that there will be no excessive stress upon any component.

While it is undoubtedly true that a body specially built for a work has advantages that appeal to many, and for many purposes is a necessity, there are many kinds of service for which what are known as standard bodies may be utilized with excellent satisfaction, and many of the manufacturers of motor wagons and trucks produce such equipment and are ready to provide it if desired. The special body is necessarily more expensive than one produced to stock specifications, and while the difference in cost is no real reason why the latter should be preferred, there is no doubt that equipment furnished by the builder of a chassis of known quality is well installed and is constructed to

conform to all the characteristics of the machine. By that is meant that the load, if reasonably distributed, will not be excessive, and the use of the vehicle will be more satisfactory than were it fitted with a body that is built to meet a purchaser's ideas and without regard to the requirements of the design.

The following tabulation of motor vehicle body dimensions, which is reproduced through courtesy of the Commercial Vehicle, New York City, is a compilation of detail supplied by manufacturers and is extremely simple and comprehensive. It is a classification of the machines regarded as standard in the market and these are arranged in alphabetical order under divisions by capacity, giving, wherever possible, the length and width of bodies for which the chassis are adapted, or the proportions of stock bodies furnished. In some instances, where enclosed bodies are provided, the height of the equipment is stated. In addition, the chassis price and the prices of the stock bodies are given. In the manner presented this is a complete guide for the person desirous of making comparisons of vehicle and body data.

SPECIFICATIONS OF 1914 ELECTRIC TRUCKS.

THE following tabulation gives the principal specifications of the different models or types produced by 17 of the leading manufacturers of electric service vehicles. The table includes 63 different sizes of machines, ranging in capacity from 500 to 12,000 pounds, and each different make is given in the order

of sizes. The information is presented as complete as is practicable, for with the majority of the manufacturers there are different options given.

These options apply particularly to battery equipment, although many of the builders regularly supply a single make, unless otherwise specified.

PALMER-MOORE EXHIBIT.

During the automobile show at Syracuse, N. Y., Feb. 23-28, one of the features was an exhibition made by the Palmer-Moore Company of motor delivery wagons driven by both air and water-cooled, two-cycle engines. The company displayed a chassis with air-cooled engine and planetary transmission gearset fitted with a four-post body, a chassis with a water-cooled engine and sliding gear transmission gearset with an express body, and a chassis of the second type named for demonstration in the show, and in the street demonstration chassis with water and air-cooled motors and sliding transmission gearsets, the former with a four-post express body and the latter with an open express body, were used.

The company now utilizes practically all of the four-acre plant of the Syracuse Stove Works in North Geddes street, which was purchased for manufacturing purposes, and where its executive offices are now located. This factory is stated to be one of the best equipped in the country for the manufacture of light delivery wagons, and the company is now prepared to meet practically any demand that may be made upon it for its products. The purpose is to build machines that will be suited for every requirement for light delivery.

WANT MOTOR 'BUS FRANCHISES.

Three different concerns, or representatives of prospective organizations, are seeking franchise to operate motor omnibus public lines in Chicago. One of these is the Chicago Automobile Transportation Company, which is promoted by Edward F. Dunne, Jr., who is said to represent Richard W. Meade of the Fifth Avenue Coach Company of New York City, R. A. Madelik of the General Omnibus Company of London, and James M. Carples of New York. Another is the Chicago Motorbus Company, which is said to be the project of R. R. and S. L. Conklin of New York City, and the other is composed of Chicago men who believe there will be a satisfactory profit from the venture.

The Detroit Battery Company has been organized at Detroit, Mich., for the purpose of producing storage batteries of differing types, and a plant is to be located at Greenwood avenue and the boulevard. N. G. Beamer has been elected president and general manager, William Ducharme vice president and treasurer, and George R. Beamer, the organizer, secretary and sales manager.

Ward P. Haines, who was for a considerable length of time advertising manager of the Anderson Electric Car Company, Detroit, Mich., maker of the Detroit electric pleasure and service wagons, has resigned that position. He has not announced his future plans.

MAIS COMPANY CLEAR.

Truck Company's Creditors Paid and New Organization in Control.

The Mais Motor Truck Company, Indianapolis, Ind., which has been controlled by a receiver since July, 1912, has paid all of the claims held by the receiver and the business is now in the possession of a company which has assumed the same name. Having freed itself from all outstanding obligations the concern is now said to be in excellent financial condition and the executives propose to promote business as actively as conditions demand. The company is now in charge of these officers: President, H. G. Francis, Rushville, Ind.; vice president, W. M. Pearce of the Innis-Pearce Company of Rushville, Ind.; secretary and treasurer, A. S. Lockard; superintendent, L. A. Caswell; purchasing agent, J. S. Sinclair.

The plant of the company is in excellent condition for manufacturing and is well equipped for all demands. The statement by the company is to the effect that the prospects for business are excellent and a considerable number of orders have been received for spring delivery, which insure constant factory activity. The company does not purpose to extend its line, but will produce the 1.5, two and three-ton machines, which will be built to the well known Mais design.

In connection with the reorganization there was delay through appeal by some of the stockholders from the order by the court for the receiver to distribute the assets of the company, but this order was later affirmed and carried out.

BID FOR GALION ASSETS.

A proposal has been made through the court for the purchase of the Cleveland-Galion Motor Truck Company of Galion, O., maker of electric internal service trucks, which has been in the hands of a receiver. W. J. Geer, in behalf of capitalists of Galion, has proposed to pay \$23,000 for the assets of the concern in installments of \$2500 on approval of the proposition, on delivery of the bill of sale, and at intervals of 30 days.

The statement is made that the Stanley Motor Carriage Company, Newton, Mass., is developing steam vehicles for freight transportation. The company has for several years adapted its machines for such purposes and the report probably originated in experimental work in the development of a steam tractor.

The American Electric Company has been incorporated at Augusta, Me., by Frederick A. Rand as president and Theodore Huss as treasurer, with capital of \$1,500,000, for the purpose of exporting, importing and generally trading in automobiles and their accessories.

ENGINE MANUFACTURERS MEET.

Standardization of Motors Urged and Exhibition at Shows Discouraged.

The Automobile Engine Manufacturers' Association, which was organized at Cleveland, O., early in December, with the stated purpose of promoting the interests of the industry, has inaugurated its activities systematically, these being determined at a meeting held at Chicago, Jan. 28. The association has made contract with M. Wulpi, who as commissioner represents several organizations of manufacturers, conducting a central bureau for them at 605 Monadnock building, Chicago, who will be the agent of the organization in that city.

The first general meeting was held at the Congress hotel, Chicago, Jan. 28, when 20 representatives of motor manufacturing concerns partook of a dinner and gave over the evening to informal discussion of shop subjects, one of the purposes being to learn the trend of opinions with reference to conditions generally obtaining.

The following day a business session took place, at which the affairs of the organization were considered and determinations were arrived at on several matters of importance. The committee on contracts made extended report in which was pointed out the fact that the industry experienced material losses through weaknesses in contracts, and suggested that this condition ought to be changed so far as possible. After consideration the association decided to recommend a form of contract that would be much more specific and decidedly stronger.

The subject of standards was considered at length and the members as a whole approved the proposition to standardize products so far as this may be done practically. The losses suffered through the deferring of contract shipments were discussed and it was proposed that this condition could be remedied on the basis of remunerative charges. This suggestion will be worked out to a satisfactory determination. Credits was a matter thoroughly discussed and with a view of safeguarding the interests of the members to the greatest extent possible. A proposition to prosecute all defalcations was generally approved and decision was reached to make public all attempts at imposition for the purpose of safeguarding the members of the association. The meeting considered from every aspect the exhibitions made in connection with automobile shows, and the prevailing opinion was that the results did not justify the time given to them and the expense incurred in preparing and exploiting the exhibits. To reach a satisfactory conclusion the meeting voted to canvass all motor manufacturers with an understanding that on the basis of replies received decision will be made whether or not to abandon exhibition at shows. The association now represents about 60 per cent. of

motor manufacturers of the country and about 85 per cent. of the entire output of the industry. The next meeting will take place at Chicago, March 20.

TAXICAB COMPANIES TO MERGE.

The Yellow Taxicab Company and the Mason-Seaman Transportation Company, which are the two largest competing taxicab companies in New York City, each being capitalized for \$5,000,000, are to be consolidated as soon as plans have been perfected, the merger having been approved by officials of both concerns and needing only the ratification of the stockholders. The Yellow Taxicab Company was formed by merging the New York Transportation, New York Cab, Connecticut Cab and Keeton Cab companies, and the control of this concern is held by Albert F. Rockwell, president of the New Departure Manufacturing Company, Bristol, Conn., and H. H. Schwartz is president. Charles R. Mason is president of the Mason-Seaman Company. The new organization will probably include some of the officers of both concerns. The consolidation is expected to result in material economies and larger profits.

MOTOKART CAPITAL \$500,000.

With capital named as \$500,000 under the New Jersey law, the Motokart Company of New York City has been incorporated, and the concern will take over the Tarrytown Motor Car Company, Tarrytown, N. Y., and the Steinbock Engineering Company. The Tarrytown Motor Car Company has manufactured and marketed the small delivery wagons, known as the Motokart, for a considerable period, and the engines and some of the components for the machines have been produced by the Steinbock company. The consolidation of the two concerns and the unification of the organization is expected to result in material economy and afford greatly needed expansion in a rapidly developing market.

The Continental Motor Manufacturing Company, Detroit, Mich., which is one of the largest manufacturers of motor vehicle and motor yacht engines in America, has begun a campaign for European business. It is to establish branches abroad, the first of which will be in Paris, France, in charge of R. A. Rothermel. The purpose of the company is to have service stations in connection with each branch it establishes.

A service station and assembling plant for the Gramm-Bernstein Company, in Tacoma, Wash., is now being erected. The building is to be of brick, two stories, 60 by 100 feet, and will have a salesroom on the first floor and a machine shop and assembling room on the second. The shop will have capacity to assemble eight trucks weekly.

BOSTON'S TRANSPORTATION PROBLEMS.

Night Haulage and Designation of Specific Routes for Cross-Town Traffic, with Systematic Control, Suggested for Relieving Day Street Congestion.

By William W. Scott.

BOSTON'S Transportation Problems" was the subject of the address made by W. W. Scott of MOTOR TRUCK to the New England section, Electric Vehicle Association of America, at a meeting the evening of Feb. 25 in the Edison Auditorium, 39 Boylston street, Boston, and as the title implies the consideration was of the conditions obtaining in the city and its suburbs. In one sense New England is affected by the situation from the fact that Boston is the second port in the United States and is a commercial centre of international importance, and a very large volume of business is concentrated and distributed from it.

Boston is peculiarly situated with reference to topography, and all traffic entering, leaving or going from one point to another within the city is concentrated on a few streets. The thoroughfares of the older portion of the city, in which a very large part of the business is transacted, are narrow and crooked, absolutely inadequate for the requirements of the day, and movement through these during business hours is necessarily slow and materially impeded by obstruction by loading and unloading vehicles, while sidewalk travel is equally retarded.

There are no direct channels for traffic across the city from the differing points of loading and unloading, and haulage from the wholesale district, the railroad terminals, docks, piers, manufactories, shops and stores are by circuitous routes, which cause material loss of time and decidedly increase the cost, and there is no system of supervision and control. Because of these conditions, which were described with a large map of the city, the application was chiefly directed toward possibilities for improvement practical through night haulage, through defined routes across the city, through

the regulation of traffic in these routes, through the inauguration of a systematic distribution with central receiving stations and suburban distributing stations by route vehicles, and by the use of motor equipment that would largely economize the street space now in use.

Following the address the conditions specified and the practical application of some of the suggestions for improvement were discussed to considerable length. The address in part follows:

I desire to emphasize that to bring about even reasonable conditions—such as obtain in cities that have been developed within a half century—is practically impossible. This could only be done through a systematic reconstruction that would be prohibitive in cost, and would be resisted by very large interests that could only regard the immediate future at the best.

But there is another aspect, that of providing for what is absolutely necessary if the city is to be developed as is hoped for, and as is desired, by the various civic, industrial and commercial organizations.

The time will come, no doubt, when every building will have facilities for shipping and receiving on private property, and this will eventually lead to system by which the occupants can be best convenience, but with rare exceptions such buildings have not yet been erected. The purpose of the builders is to utilize all of the available area for the use of the tenants. The Houghton-Dutton Company in 1904 erected the building at Beacon and Ashburton streets and vehicles can be driven into and from this at Ashburton street and loaded and unloaded, without interfering with traffic. This, to my knowledge, is the only instance in Boston where a firm has voluntarily made provision to handle its shipping and receiving off the public streets, and I believe I am right when I say that the company never made a better investment. There are properties so located that such provision could not be made, but any business of proportions must be established where every desired facility can be provided.

Some Congestion Inevitable.

There are conditions where congestion appears to be inevitable and a solution that would afford sufficient passage for traffic would apparently cause decided hardship. One of these obtains in North and South Market streets, about Quincy market and Faneuil hall. Many of the people doing business in this locality are in stores so small that you wonder why they are there, and the only conclusion is that they believe they have advantage in being in what is regarded as a centre. In a very small area hundreds of vehicles are usually standing, and movement through them is possible only with material delay. This congestion is extreme at times. If the vehicles were limited to the number that could be backed to the walks for loading or unloading, provision would have to be made for those waiting for places, and there is no logical place where the excess could be held. There are certain times in the day when the number of vehicles is comparatively small, and a possible improvement would be

Business District of Boston, Showing the Cobweb of Narrow and Crooked Streets Between Charles River and Fort Point Channel, with but One Direct Route (Washington Street, Shown by Heavier Shading.) Through City from South to North—Greatest Congestion Is Within the Area of Which the Postoffice, Indicated by Black Circle, Is Centre—Black Blocks Represent the North and South Stations, Shaded Blocks Common and Public Garden, and the Small Outline Circle the State House—Top of Map Is Approximately North.

to assign vehicles to places during stated periods, requiring loading and unloading during those assignments, which regulation could be worked out with practical supervision. Another possibility would be the location of the stores and the shops in adjacent streets, but this could not be accomplished without concerted action and the co-operation of all interests, and I believe you will agree that the task of adjustment would only be possible through legislative authority and municipal control.

You who live in Boston and vicinity do not realize how greatly business competition has increased the street traffic. You may go into the Jordan-Marsh Company's store at 4, order your purchase sent to Salem, for instance, and it will be delivered at its destination early in the evening. You may make a purchase at practically any of the stores at the hour of closing to be delivered in any locality within the 10-mile radius of the State House, and delivery will be made that day. The same condition applies to purchases made for delivery within the "city proper", which is defined as that section of Boston north of Fort Point channel and east of Massachusetts avenue, taking in a small section of Brookline. This delivery is made by the private equipment of the stores and approximately 350 different organizations engaged in transfer work.

The League of Express Companies is composed of about half the concerns doing expressing or haulage business, but this does not include those engaged in heavy transportation. Were these added the total would probably be increased by 100. Besides these two classifications there are those who do individual or incidental transporting—an unknown number. There are four general companies that do a business extending all over the country, there are 15 that do what may be regarded as a New England business, and the remainder serve the city and the suburbs.

There is an enormous duplication of service. One does not really understand how great is this duplication until one knows that in some instances as many as 24 different concerns are serving a single locality, to say nothing of the General Express companies' distribution and the incidental services. This means that while competition reduces prices materially the street traffic is proportionately increased. Many of these companies are concerns of considerable proportions, well organized, doing remunerative business, and, assumedly, making reasonable profits. Many that serve suburban districts have regular contracts with the big stores. The Jordan-Marsh Company, for instance, does business with at least 40 of them, to say nothing of its own equipment. These companies in many cases have regular traffic agreements and exchange business. One of the features of the transportation organizations of Boston are the offices of the General Express Company, which is a clearing house for more than 100 small companies that rent a box, have clerical service, have goods received for them, and unitedly pay for service that they could not otherwise obtain at great expense. Such facilities have promoted the growth and preserved the existence of many of these small concerns, and collectively they are a factor of material importance.

Transportation at Night.

Considering the conditions from another aspect we find that the traffic may be differentiated into classifications. These may be stated, without reference to importance, to be haulage to and from the docks and piers, from the wholesale houses to customers, to and from the freight terminals, from the coal yards and docks, the haulage of construction material, of the express companies and of the large stores, and added to this the casual or incidental requirements. I have only outlined these, and to point out that a very large part of the heavy transportation could be done at night. I am convinced that it would be intensely practical to do a great deal of the haulage by night at less expense than is now paid for day work. I say this advisedly, because when the proposition is considered one realizes that only five nights would be available and practically six days' work would need be done in five.

But night haulage would mean more than the mere use of vehicles if the purpose were to eliminate all of the traffic possible from the streets. We know that freight trains are generally operated nights because the greatest number of passenger trains are operated days, and this necessitates handling the bulk of the freight at the terminals by day. That a great deal of the haulage by street vehicle is during business hours was also an important factor. Vessel sailings are generally by night to convenience those who do not care to lose the business part of the day, and for the more convenient handling of the freights. I do not believe that it would be practical to advocate radical changes in leaving times of water lines, but there is no reason why freight could not be hauled to and from the piers, to and from the freight yards, and while this might necessitate adjustment of the working hours of men in warehouses, in large stores, in piers, in the terminals, I think this could be brought about without hardship. There would, however, be large accumulations of freight between Saturday mornings and Monday nights if this form of haulage were only done by night.

A great deal of the coal, ashes, supplies, etc., for the office buildings, could be hauled nights, and there is no good reason why some construction material could not be delivered between 6 at night and 7 in the morning, although the absence of light would probably prevent all of this work being done. Better street lighting and regulation of the traffic would be essential. It would be impractical to expect much of the suburban delivery to be done nights, because the volume of any given business would not be sufficient to justify the constant presence of men to care for the loads when delivered. While there are limitations of what haulage could be done, there is no doubt that a considerable volume could be eliminated from the day traffic.

Reorganization of Service.

Night haulage would mean the reorganization of some of the services. I mean that the presence of day and night shifts would mean doubling the supervision and the constant attendance of those keeping record. Arrangement would be necessary for the receipt of loads delivered, and unless the haulage was of sufficient volume those requiring the work would not be willing to co-operate. The economy for the owners of vehicles must be considered from this aspect as well. There is no doubt that transfer work from warehouses, piers, terminals, to stores, and vice versa, if done at night, could probably be contracted for. I mean that this would afford opportunity for concerns to make contract for haulage, and this would mean economy for every interest.

If the people of Boston could be satisfied with delivery within a reasonable time after purchase in any of the stores of importance, there is no doubt that a great deal of the haulage into the suburban points could be done at night. This would mean the establishment of stations in different localities where the goods could be received, sorted and distributed. Let us assume, for instance, collections made in any given section, carried by trucks to a point where a general station were located, received, sorted and distributed from that station, the distribution being by route. This would simplify conditions immensely, eliminate a great deal of equipment and would minimize expense.

Boston has had an experience with a proposition of this kind on a very limited scale when the Boston Auto Express Company was established in December, 1900. The company purchased six electric vehicles and 16 gasoline machines and established stations in Chelsea, Brighton, Dorchester and Somerville, hauling the packages for a number of the stores from a central station in Boston. Despite the crudity of the machines and the handicap of the illness of the executive, an excellent organization was developed, and had there been available the same quality of equipment as can now be procured there is no doubt that it would be in existence today.

There are conditions that militate against such a proposition, among them being the sending of goods for approval, C. O. D., for examination, the handling of complaints through an intermediary instead of direct, and the impossibility of a store to preserve its individuality with its customers, and not dealing with them direct, but as against this one may point to the economy and to the fact that for 42 years one concern has engaged in parcel distribution in Boston and served the people to their satisfaction. I refer to the Boston Parcel Delivery Company. There are other companies not doing as large a business, but, I believe, these are equally successful.

The establishment of the suggested suburban stations would not be practical if the purchasers expected delivery as quickly as they do now. Such a system would be practical for distances of from 20 to 25 miles from Boston, but this would probably mean the delivery each day of the sales of the previous afternoon and of that day up to noon. One result would be the elimination of many of the so-called express companies. Distribution of this character would necessarily be undertaken by a concern of large resources, well organized and prepared to develop a business of substantial proportions.

Considering One-Way Streets.

One means of regulating traffic has been by establishing one-way streets, and while these undoubtedly reduce the number of vehicles materially, this is accomplished by causing other traffic to travel further, with corresponding delay. The benefit may be obtained, but it is at the expense of others who are undoubtedly entitled to consideration. Much better results could be obtained by prohibiting loading and unloading in congested streets during specified hours, by designating routes from one section of the city to another and having supervision that will keep this traffic moving, giving the route traffic precedence over that from certain side streets. We can learn a fact or two from London, where in the main routes the traffic is not held to permit the crossing of the traffic from the side streets. Vehicles from side streets are required to turn into the main route and leave it one or more blocks beyond. This might be applied where needed.

The street commissioners of Boston have supervision of the traffic, I believe. That is, the commission determines the regulations, which are enforced by the police. I am inclined to believe that this body would be glad to receive suggestions from those who have studied conditions and submit them for consideration. I believe that a committee of this section, from the Electric Motor Car Club, from the motoring organizations, and from the different civic bodies, the Chamber of Commerce, for instance, should consider the subject of better traffic regulation, and after study from every angle determine what will apparently best meet the conditions. With this as a basis the people as a whole can be educated. Time will be necessary, but the earlier the work is begun the better the results will be. Municipal and perhaps state legislation may be required. The streets are used more each year and safety is the first factor. The next is economy.

The possibilities for street economy through the use of motor vehicles are so obvious that I have felt that discussion of their use is almost needless, but without possibility of any other relief than by means of motorized equipment the haulage of Boston could be done with less than half the number of vehicles now utilized, and when you realize that a motor wagon or truck requires about half the street space required by animal transports of similar capacity you will see that such a transformation would be a wonderful progression. In other words, the haulage of Boston could be done with the use of about 25 per cent. of the street space now necessary for the actual needs of traffic.

ROAD BUILDERS' OFFICERS.

The new officers elected by the American Road Builders' Association at the annual meeting held in New York City recently, include the following: President, W. A. McLean, a commissioner of the department of public works, Toronto, Ont.; first vice president, George W. Tillson, Brooklyn, N. Y., consulting engineer; second vice president, A. W. Deane, Boston, Mass., chief engineer, Massachusetts highway commission; third vice president, Austin B. Fletcher, Sacramento, Cal., state engineer, California highway commission; secretary, E. L. Powers, New York City, editor "Good Roads"; treasurer, W. W. Crosby, Baltimore, Md., consulting engineer.

GOVERNOR JOINS AUTOMOBILE CLUB.

Governor Walsh of Massachusetts has become a member of the Bay State Automobile Association of that state, being elected to honorary membership following his entertainment by the association and a conference with leading members relative to the motor laws of the state. As the Bay State Automobile Association is identified with other organizations of owners of motor vehicles in discouraging hostile legislation proposed, and in promoting measures that will be beneficial, the members believe that they will receive consideration from the governor, before whom all laws must come for approval, even if denied that courtesy by the legislators.

The Maxwell Company has succeeded the Western Parlor Frame Company at Plymouth, Wis., and will, with capital of \$25,000, begin the exclusive production of bodies for motor equipment for undertakers' use. Hearse bodies will be built to specifications for individual customers, and to standard designs for the requirements of motor vehicle manufacturers. The company is stated to be the only concern that is manufacturing the specialties stated.

The Little Giant Truck Company of Boston has been established at 221 Columbus avenue, Boston, Mass., as factory branch of the Chicago Pneumatic Tool Company, and the business is in charge of Gentry Clark, who was formerly identified with the Garford branch in that city.

J. J. Martin, who was for a year and a half connected with the Commerce Motor Car Company, Detroit, Mich., has been appointed district manager for the Middle Western States for the Stewart Motor Corporation, with headquarters in Chicago.

The Nashville, Tenn., branch of the Goodyear Tire & Rubber Company has been placed in charge of W. E. Dermot, who was for several years connected with the motor truck department of the company located at Akron, O.

KNOX PROPERTY FOR SALE.

Springfield Plant and Equipment Offered in Market as Going Concern.

The entire property of the Knox Automobile Company at Wilbraham road and Waltham avenue, Springfield, Mass., consisting of the site, factory buildings, machinery, fixtures, supplies, parts and automobile vehicles finished and in process of manufacture, has been offered for sale by Charles G. Gardner, trustee in bankruptcy, and will be disposed of either at private sale or public auction, this having been authorized by the United States district court. This property is one of the best of the kind in America, being so located that the west side abuts the property of the New Haven railroad, the company having the exclusive use of a spur track extending the full length of the factory, a distance of about 800 feet, this affording the best of shipping and receiving facilities. The factory buildings are of brick, one and two-story, approximately 800 by 115 feet, and the floor space is 241,355 square feet, or about 5.5 acres. The land and buildings have been appraised at \$323,803.41, and are subject to a mortgage of \$36,900, and the machinery and equipment have been appraised at \$365,404.44, this giving a total valuation, less the mortgage, of \$652,217.85. The drawings and patterns and the merchandise inventory are valued at \$896,274.24. The total assets of the company are stated to be \$1,634,414.89.

The company has been operated in bankruptcy since Jan. 21, 1913, and from that date to Feb. 20, under a trustee, it did a gross business of \$1,250,242.41. During the past few weeks the number of sales has increased and the prospect for future business is decidedly encouraging. During the period stated the company has specialized the manufacture of Knox-Martin tractors and fire apparatus, selling 48 pieces, and 112 tractors, the total selling price being approximately \$661,000. The company, as it now is, is regarded as a going concern, there being a large demand for parts for Knox cars throughout the country, these machines having been produced for about 13 years. The plant is fully equipped for the manufacture of motor vehicles of all kinds. By vote of the directors the purchaser of the plant will acquire the good will of the business and the right to use the Knox name. Proposition for the purchase of the whole or any part of the real estate or personal property will be entertained by the trustee, who may be addressed at Wilbraham road, Springfield, Mass.

W. S. Campbell, formerly connected with the Iron Trade Review and the Daily Iron Trade as circulation manager, has been appointed advertising manager of the Miller Rubber Company, Akron, O.

The Swinehart Tire & Rubber Company, Akron, O., has appointed J. G. Cass manager of the company's branch at Cleveland, O.

The MOTOR TRUCK

Devoted to Motor Driven Business Vehicles of All Classes.

VOL. V.

PAWTUCKET, R. I., APRIL, 1914

No. 4

BUYERS FLOCK TO BOSTON TRUCK SHOW.

**Productiveness and Promotive Value Very Large, the Attendance Exceeding All Records---
Few Innovations Shown, the Builders Generally Standardizing or Specializing
a Single Type---Several Adopt Foreign Practise.**

REGARDED from any point of view—the representation of the industry, the volume of business transacted, the attendance, the interest of the people, or the specific promotion of highway vehicle transportation—the third annual exhibition of motor vehicles, organized by the Boston Commercial Motor Vehicle Association, at Mechanics' building, Huntington avenue, Boston, March 17-21 inclusive, was a success. As a matter of fact it was more than a success when one considers the conditions in which it took place—that is, the attitude of the Automobile Chamber of Commerce and the Motor and Accessory Manufacturers, for both these organizations classified this and the pleasure car show as "local"

displays and refrained from supporting them, the members being prohibited from participating save through the representation of agents.

The Boston pleasure car shows have invariably been larger than either the New York or the Chicago exhibitions, gauged by number of vehicle exhibitors, number of vehicles shown, business transacted and attendance. The Boston truck shows have been

large and productive, exceeding from every point of view the exhibitions elsewhere. But these proportions, and their actual promotive value to the industry, for New England today owns from 12 to 15 per cent. of the entire number of motor wagons and trucks in actual service, were completely lost sight of, and the shows, because they were controlled by the

local associations, were designated "local".

It may be well to explain that the Boston Commercial Motor Vehicle Association is composed (as is the Boston Automobile Dealers' Association) of agents for manufacturers and direct representatives of those maintaining branches, and these organizations have assumed all responsibilities, financed the shows, and, naturally, shared

the profits. When the magnitude of the exhibitions—they have for years been the largest of the country—is considered, the business possibilities must be such as to justify them, and the policy that would restrict them cannot be regarded as being anything else than shortsighted, for the endeavors of the agents and representatives are shared proportionately by builders of vehicles. Whatever measure of success they attain

General View of Grand Hall from the Balcony, Showing the Principal Truck and Wagon Exhibits on the Main Floor.

The Exhibit of the R. & L. Company, Which Included the Garford Trucks and the Willys Utility Delivery Wagons.

must necessarily be with equal profit to the industry, and supposition that limiting publicity and promotion will be to the benefit of a few is not well founded. As to the direct profit of those who sell accessories, supplies or equipment, there is no doubt that the greater the volume of sales the more the manufacturers and selling agents will benefit.

The Boston truck show was promoted by the members of the association because they, having accurate knowledge of the market and the conditions in which they do business, had confidence in the financial possibilities and were willing to assume all responsibilities and obligations. The exhibition was organized on sane lines, and the only reason for it being in any way identified with the pleasure car show was the fact that the time selected was the most propitious of the entire year for promoting the sale of haulage equipment, when the plans for the season's activities have been determined and preparations must be quickly made. Logically, business men could not be expected to invest capital in motor vehicles in January when these would not be needed for at least three months, and yet this was the belief of those who had organized motor truck exhibits in New York and Chicago. The motor truck show of a year ago was a success, despite the fact that those held more than two months previous were not especially productive to the exhibitors.

Productiveness has been a characteristic of all Boston's exhibitions. They have been regarded as real trade institutions, and the number of transactions has always

been large, for in addition to Boston and its suburbs visitors have been attracted from the six New England states and from the Canadian provinces. Motor vehicles are no novelty and their usefulness and utility are thoroughly understood, and the proportion of persons attending the Boston show who purpose to buy is extremely large. The real advantage is to see a considerable number of machines and compare them in conditions that are favorable for comfort and convenience. For any man to examine as many vehicles as were seen at the Boston show and understand

them thoroughly, would require as many days as hours were necessary in Mechanics' building, to say nothing of the actual expense and loss of time, as well as other material factors. Few persons will devote time to inquiry into the relative merits of service wagons without a motive, and it is also apparent that the real promotion possible from the personal interest of those visiting the shows is of material importance. By this is meant that the men who go to exhibitions of vehicles with the purpose of informing themselves of such types as will meet their requirements, usually influence their associates and friends, and for this reason they do a great deal of promotive work, the value of which depends largely upon the quality of the information they have gathered.

The Boston motor truck show of 1914 was interesting from many aspects, and so far as attendance is concerned it was record making. The statement that

Republic Delivery Wagons Shown at the Stand of C. J. Fischer, the New England Agent, Located in Exhibition Hall.

approximately 50,000 persons visited the building during the five days the show was in progress is official, and demonstrates that the exhibition was attractive to a very much larger number than would be assumed.

The number of vehicles disposed of during the show was large, but estimate is not practical because sales were consummated that had been negotiated previous to its opening, and many transactions will undoubtedly result from inquiries made while the exhibition was progressing. The overlapping of the transactions precludes anything like the whole number being stated with accuracy, but the exhibitors as individuals were unanimous in their estimate—that the show was not only productive beyond expectations, but the stimulus to business would be realized during the entire season. Experience had demonstrated to the exhibitors that if they were to regard show sales only as results, and failed to consider the prospects that had been attracted and interested, they were probably very wide of the mark.

The show as a whole could be designated as a "selling" exhibition rather than one at which agencies were made, although many of the New England agents and factory branches established representatives in such sections as were desirable. Some of the visitors who sought to make connections with manufacturers were forced to do business with the district or section agents, because of the policy of some to have representation by sub-agents, and were disap-

The Exhibition of the Myer Abrams Company, New England Agent for the Lauth-Juergens Delivery Wagons and Trucks.

pointed in not being able to secure as advantageous terms as were desired, or which would be possible through direct selling.

The show was made up of the exhibits of 33 different manufacturers, and included 32 makes of gasoline, two of electric and one of steam driven vehicles, and at the stands were seen 35 different makes of machines, there being 155 chassis, of which 116 were equipped with bodies, the stripped chassis exhibited being otherwise complete. In addition to this there was a machine not shown by its maker, but exhibited by the firm that constructed the special equipment mounted on it. As this apparatus was valued at approximately \$2500 aside from the chassis, it will be seen that this was of considerable importance. In the streets a considerable number of machines were used for demonstrating purposes, these being generally of the same types shown on floors of the halls. The number of vehicles practically filled the main floors of both

Grand and Exhibition halls, and the displays were confined to machines, there being very few parts shown. In fact, the show may be said to have been of chassis ready for the road, and of special bodies, which experience has demonstrated are the factors that have special interest for the buyers.

The exhibition was made with the elaborate decorations that were designed for the pleasure car show, and while these were pleasing to the eye, they were largely a matter of indifference to the visitors, and of really no practical value to those who came to examine and study the machines. Had

Where the I. H. C. Machines of Two-Cylinder High-Wheeled Construction Were Displayed in Exhibition Hall.

The Main Aisle of Exhibition Hall. Looking Toward the Principal Entrance, Showing the Kelly and I. H. C. Exhibits in the Foreground.

they been specially prepared for the show they would have been an extravagance, but because of being an inheritance from the pleasure car display they were a pleasing setting. As a matter of fact, what is especially desirable in an exhibition of this character is abundance of light and both sections of the building were well illuminated.

Show of Standard Productions.

When one considered the character of the exhibition it was noticeable that it was practically made up of machines that are known throughout the industry. The concerns represented were generally large and well established, and there were comparatively few new comers. There were but two electric manufacturers included in the exhibitors, as against eight that made display a year ago, and as one of these also produces gasoline machines in very large numbers, it will be seen that the electric service vehicle industry practically withdrew from participation, this making a considerable difference in the total of exhibitors. Comparing the lists of exhibitors of this show with that of a year ago, one finds that no less than 12 have discontinued production or no longer exist, and 10 of these built gasoline machines. There were but five exhibitors that could be regarded as new to Boston, and of these but three are new concerns, one being established about a year ago.

The show was noteworthy from the fact that there were no freaks and the constructions could be regarded as in every way conventional. There was but one vehicle of the cyclocar type shown, and this, being displayed near some of the largest machines in the exhibition, appeared practically like a toy in comparison. There

was one machine of the light car class exhibited, this being designed as a package wagon. Both these exhibits showed the evidences of hurried preparation for the show, but despite this fact they attracted much attention and were decidedly interesting.

Concentrating on Standards.

Considering the mechanical aspects of the exhibits one may summarize in the statement that practically all the manufacturers have concentrated on standards and have generally adhered to one design, although machines may be made

in different sizes. In some instances there is variance with reference to minor details, but as a rule standardization appears to be the general object, this making for greater manufacturing economy and simplification of production.

Two manufacturers continue to use the horizontal two-cylinder opposed motor, these being the Autocar and the International Harvester, and these machines are practically unchanged. The designs have been continued, the Autocar with the motor mounted transversely in the chassis frame, and the I. H. C. with the motor installed longitudinally. Two others, the Parcel Post and the Merz machines, use two-cylinder motors, but these are the vertical V type, with the cylinders at an angle of 45 degrees from each other. The Autocar and the Merz are the only two in which there is no option for the purchaser, as the I. H. C. machine is supplied with either water-cooled or air-cooled motors, and the Parcel Post is built with either a two-cylinder air-cooled or a four-cylinder water-cooled engine. The Parcel Post wagon exhibited was driven by a two-cylinder, air-cooled motor, and for this reason

The Display of the General Motors Truck Company in Grand Hall, Showing the Special Body Built for the Animated Advertising Company.

the classification stated is given.

The Autocar and the I. H. C. machines have been built to practically single designs and have been standards in the markets for a number of years. The Merz was designed as a cyclecar and the utilization for light delivery is regarded as practical, although the possibilities have not yet been demonstrated by material service. The Parcel Post Kar is another new production that has been worked out with the purpose of being specially suited for quick distribution of light loads.

Two Types of Three-Cylinder Motors.

There were two makes of three-cylinder motors exhibited, and both of these were of the two-stroke cycle types. The one was the well known Chase engine, which is probably one of the best known of the air-cooled type now in use, having been built without change for six years, and the other was the Palmer-Moore, that shown, however, being water-cooled. These motors are distinct in characteristics, the Chase being a conventional construction of the three-port design, while the Palmer-Moore is fitted with large area inlet ports that may be varied by means of rotary shutters, this affording a variable supply of fuel that will yield efficiency at any engine speed, from idling to the heaviest work. The Palmer-Moore motor is built both air and water cooled, there being practically no difference in construction aside from the jacketing of the cylinders, but the water-cooled engine is a comparatively new product.

Four-Cylinder Heavy Duty Motors.

There were in addition 28 makes of vehicles equipped with different types of four-cylinder vertical

The Exhibit of the Knox Automobile Company, Grand Hall, with a Knox-Martin Tractor and Trailer with Dumping Body.

water-cooled motors, all of which were designed for heavy vehicle service, the majority having strokes somewhat in excess of the bore. Practically all of the manufacturers either use an engine built by a firm specializing them, or have developed their own design, there being no inclination to accept what has not been proven in all operating conditions. With reference to the motors the purpose of the designers is limitation of speed to minimize vibration and to secure satisfactory power production with practical fuel economy. There is realization that the public generally understands the capacity and utility of the four-cylinder construction, and there is no reason to undertake to educate the people to the qualities of what they are not familiar with. There is, of course, material variance with engines of conservative design, with reference to bore, stroke, valve location, lubrication and cooling, to say nothing of control, governing, ignition and other important factors, so that the motors have as much to interest as though they differed widely in principle.

There is no doubt, however, of the education of the industry to the necessity of heavy construction, a quality that was particularly noticeable in the heavier machines, for great strength and large bearing surfaces for all contacting and wearing parts is recognized as being absolutely essential for the long endurance demanded and required of service vehicles, and as the only certain insurance against economical maintenance and upkeep. This influence was reflected in the motors as well as in other details.

There were comparatively few worm and gear driven machines, these including the Pierce-Arrow, which is the only type built by the maker; the 3000-pound Universal, both of which are well known, and the 3000-pound Atterbury

The Palmer-Moore Delivery Wagon, Equipped with a Three-Cylinder, Two-Cycle, Water-Cooled Motor and Four-Post Express Body.

wagon and the 6000 Chase model O truck. The two last mentioned are new productions and were seen for the first time. While there has been no determination with either concern as to the further use of these designs, they are specially interesting. The Chase truck is a combination of American and French practice, and with a view of meeting a demand for a vehicle of recognized standards it is propelled by a four-cylinder water-cooled engine, this being a unit power plant of a Continental motor and Brown-Lipe transmission gearset. The drive is direct from the gearset through a propeller shaft to a David Brown worm and gear in a full floating rear axle, and instead of the usual radius rods the driving thrust is through the front ends of the rear semi-elliptic springs.

These springs are underslung, this making possible a comparatively flat arch, and the forward end is secured in a deep hanger that is strengthened by webbing to take the driving thrust. The rear end is free to move in a long shackle. This is probably the first time in America where the worm and gear drive

sign in that the same general idea of construction that has been described in the Chase truck has been applied to it. This machine, however, has the conventional method of coupling the driving shaft, there being two block and trunnion universal joints between the rear axle and the gearset. The springs are seated on the steel housing of the rear axle, and these are with a comparatively flat arc. The forward ends are secured in the spring hangers by large hardened steel bolts. The springs have heavy master leaves and main leaves of equal length, with eyes bushed with phosphor bronze. The rear ends are carried in spring shackles. In this machine the full driving thrust is sustained by the springs, which have not the nearly straight forward section that is so noticeable in the Chase design. The springs have very large seats and the axle housing is trussed to add to its strength.

The Walter Front Wheel Drive.

Another example of the spring being used instead of the radius rod is found in the Walter trucks, which are built under the Latil patents, and in this the front end is shackled and the rear end is pivoted in the hanger, so that the machine is literally drawn by the front wheels instead of a thrust being exerted upon the frame. It would be possible to fit forward radius rods, but experience has proven that these are not necessary, and the construction obviates the possibility of their use limiting the turning radius of the wheels. The use made of the springs in this design has been proven by years of experience, and there is no well founded engineering objection to be made to it.

The Main Aisle in Grand Hall, Looking Through the Exhibit of the White Company, Toward the Stage, on Which Was the Packard Display.

has been utilized where the traction thrust is taken wholly by the springs and the experience with the construction will, no doubt, be very interesting to observe. The springs are made with the master leaf and the main leaf the same length, the eyes being extremely large and bushed with bronze, with unusually heavy nickel steel bolts that take the drive. The main driving shaft has two universal joints, or rather flexible couplings, these being of the Daimler type, consisting of spiders with three arms each, which are bolted to three leather rings, the bolts being secured with keystone washers that equalize the stress upon the leather when the shaft is turning.

The rear axle is housed in a one-piece crucible steel casting, with squared end sections, and the worm shaft, gear wheel and differential are carried by a heavy plate that is bolted to the housing, these being removable as a unit, should occasion require work or examination.

The Atterbury 3000-pound wagon is unusual in de-

The Walter front-driven trucks were shown for the first time in Boston—in fact, for the first time in America—but a Latil truck was displayed at New York in January, 1913. The Walter truck, however, differs considerably from the foreign design, and adaptations have been made to meet conditions known to exist in America. The Walter engine has been modified to some extent. This is a very long stroke type and while the rating is apparently small, the long stroke justifies the claim of 40 horsepower. The statement made refers to the five-ton size, which was shown, for the company builds the front drive trucks in three, four, five, six and 7.5-ton sizes, and it also produces the Walter rear wheel driven 2000 and 3000-pound wagons. Because of the demand for a front wheel driven two-ton machine there is a probability that one of this size will be added. When specially ordered 3.5 and five-ton rear wheel trucks will also be built. It will be understood that it is the purpose of the company to specialize on front driven construc-

tion, but it has also designed a four-wheel-driven machine in which the rear wheels are driven by a second countershaft mounted on the dead rear axle, from a propeller shaft extended back from the transmission gearset case. This is intended for use as a tractor, because of its short wheelbase and its small turning radius, and to carry a load not exceeding four tons and draw two trailers each carrying a similar load. This is a maximum of 12 tons.

The Latil trucks are occasionally built with a chassis that is wholly mounted on the front wheels, to which it is practical to couple a frame carrying a body, to which is attached rear wheels, thus converting animal equipment, but this idea is not seriously advocated for American use. The Walter machines are constructed so that the frame at the rear is suspended on semi-elliptic springs, and these are seated on a dead rear axle, the rear wheels being shod with wide steel tires. The forward wheels are fitted with rubber block tires, the units being set diagonally in the rims. With this construction the machine may be mounted forward only on rubber tires, or on all four wheels, according to the requirements.

Another innovation is the use of brakes that operate on every wheel. The service brake, applied by a pedal, checks the forward wheels through the transmission shaft, and the rear wheels by expanding shoes in drums on the rear wheels, and the emergency brake increases the pressure on the brake shoes in the rear wheels, affording a much greater efficiency.

The Velie One-Ton Chassis.

Another new machine is the Velie one-ton wagon, which is designed to meet the requirements of those who need fast delivery of moderate capacity. This design is in every way conventional and from the sturdy construction is intended to be extremely serviceable. The machine has a 45 horsepower vertical, water-cooled, L-head motor, with cylinder bore of 4.625 inches and stroke of 5.25 inches, the cylinders being cast in pairs. The engine is with all moving parts enclosed and protected. The crankcase is sectional, the lower half containing the oil reservoir, and the upper half the main and camshaft bearings, so that the operating parts may be reached by removing the lower portion. The motor is cooled by water circulated by a large centrifugal pump through ample water jackets and a honeycomb radiator, and radiation is promoted by an 18-inch fan driven by a flat belt. The lubrication is by a combination system, the oil being drawn from the reservoir by a gear-driven pump, and the overflow forms a pool from which the motor is lubricated by the sweep of the big ends of the connecting rods. The ignition is a Bosch

dual system and the carburetor is an automatic float feed type.

The clutch is a multiple dry disc with Raybestos and steel contacting surfaces, having a single adjustment, fully enclosed in the flywheel. The transmission gearset is a selective type with three forward and reverse speed ratios, and the drive is by a propeller shaft to the full floating rear axle, there being two Spicer universal joints in the shaft. The frame of pressed channel section steel has side members 5.5 inches width and this carries a sub-frame in which is mounted the radiator, power plant, clutch and gearset. The frame is carried on semi-elliptic springs, 40 inches length forward and 50 inches length rear.

Full Floating Rear Axle.

The rear axle is a full floating type, containing the reduction gearing as well as the differential, and the shafts are mounted on roller bearings. All parts are adjustable for wear. The front axle is a drop forged heat treated I section. The wheels are wood, artillery type, mounted on roller bearings forward, and are fitted with either 34 by 3.5 inches solid shoes forward

The Stand of the Whitten-Gilmore Company, at Which Was Shown the Exhibits of Standard Trucks and Federal Wagons.

and 36 by four inches rear, or 36 by five-inch pneumatic tires. The steering gear is irreversible, of the worm and sector type, at the left side. The ignition is fixed, but there is a fuel supply throttle lever on the steering wheel, and the speed lifting lever and the emergency brake lever are at the centre. The accelerator is operated by foot pedal. The service brake, actuated by a foot pedal, contracts on drums on the rear wheels, and the emergency brake shoes expand within the same drums. The speed is 15 miles an hour. The wheelbase is 129 inches, the tread 58 inches, the clearance 11 inches and the turning radius 17 feet. The equipment includes a Gray & Davis electric starter and generator, electric head, dash and tail lamps, and electric horn.

The other sizes of Velie machines shown were practically unchanged, the principal improvement being in the size and construction of the jackshaft brakes.

The Federal exhibit was of interest in that these

The Combination Tank Truck of the Kinney Manufacturing Company, Adapted for Street Watering, Oiling or Tar Application on a Peerless Chassis.

wagons are now made with rating of 3000 pounds capacity, the parts being strengthened wherever necessary to meet the increased requirements. The L head motor, which was with cylinder bore of 4.25 inches and stroke of 4.5 inches, with the cylinders cast in pairs, has been replaced with an engine with the L head cylinders cast en bloc, with bore of 4.125 inches and stroke of 5.25, this considerably increasing the power. The radiator is changed from a vertical tube to a cellular type, and the jackshaft design from the semi-floating to the full floating construction. The jackshaft service brake has been increased from 12 inches diameter and 1.5 inches face to 13 inches diameter and two inches face, and the emergency brake on the rear wheels has been made three inches width instead of 2.5, these adding materially to the braking efficiency. The rear axle has been increased from a rectangular section two inches square to two by 2.5 inches, and the rear tires have been increased from four to five inches width. The tread of the rear wheels has been increased from 56 to 59.5 inches.

The Universal worm and gear driven chassis, which was formerly rated at 2000 pounds capacity, has been given a rating of 3000 pounds through the use of heavier components whenever necessary to strengthen the construction to carry the load. There has been no change in the design, and the power plant used is the same.

The only changes in the Stewart delivery wagon chassis, which is of 3000 pounds capacity, is the use of a Daimler type of leather flexible joint between the clutch and the transmission gearset, this taking the place of the

trunnion and block type of joint that has been used, and a plunger accelerator pedal is substituted for the lever formerly employed.

Several Republic chassis were exhibited, one of these being stripped and the others fitted with express bodies. This machine has been in the market practically a year, but this was the first time it was seen at Boston. It is a standardized 3000-pound wagon, constructed of components selected with a view of securing long endurance, and designed to afford complete accessibility

and economy of maintenance and upkeep.

One of the features of the display of Packard machines was the four and the six-ton chassis, these being two new sizes which follow the design of the five-ton type. The other Packard machines are continued with practically no changes, and these are built in 4000, 6000 and 10,000-pound capacities.

The Palmer-Moore Company, Syracuse, N. Y., showed in Exhibition hall a single machine, this being a chassis with a water-cooled, three-cylinder motor, which was equipped with a four-post express body. This exhibit attracted no end of attention from the fact that it was the first time the engine, with variable inlet ports, had been seen.

Merz Car Friction Driven Type.

The only machine fitted with the friction form of power transmission was the Merz cyclecar parcel delivery wagon. This is driven by a two-cylinder V engine of the type commonly developed for motorcycles, installed transversely in the frame, the engine shaft carrying a driving disc that contacts with a

A Section of the Stand of the New England Branch of the Velle Motor Vehicle Company, Where a Large Display Was Made.

wheel movable on a jackshaft, and the power is transmitted by V belts from pulleys on the jackshaft to pulleys on the rear wheels. This construction allows great variation of power application and speed, and the utilization of the exact energy that is necessary to perform a given work. The body is constructed with the roof extended forward to form a cab, and the driver is provided with a very comfortable seat and is well protected. The body is intended to carry 350 pounds, and has sufficient space to take a considerable bulk. For light work, where quick delivery is desired, the machine will undoubtedly serve a very useful purpose, for it can be operated and maintained at very small expense.

Little Giant Machine Redesigned.

The Little Giant delivery wagon, which has a load capacity of 2000 pounds, has been practically redesigned, the two-cylinder opposed motor being replaced by an engine of the conventional four-cylinder, water-cooled, L head type, with the cylinders cast en bloc, having a bore of 3.75 inches and stroke of 4.5 inches. The crankcase is divided, the lower section being the oil reservoir and the upper half carries the bearings, shafts, timing gear, etc. All the working mechanism is enclosed. The lubrication is by combination force feed and splash, the circulation being through a sight gauge on the dash. The ignition is by low-tension magneto and transformer coil, with dry cell battery for starting. The motor is cooled by thermo-syphon circulation through a vertical finned tube radiator. The engine is mounted in a sub-frame suspended at three points.

The clutch is a multiple disc type, operating in oil, and the transmission gearset is a selective form with three forward speed ratios and reverse. The clutch and gearset are assembled as a unit with the jackshaft, which is suspended at three points. The drive is by side chains from the jackshaft to sprockets on the rear wheels.

The frame is a pressed steel channel section four inches width, this taking the place of the truss construction formerly used. The frame is mounted on semi-elliptic springs, with a jackspring mounted above the rear axle. The axles are rectangular sections, the front two by 1.5 inches and the rear two inches square, and the wheels are 36 inches diameter with three-inch tires forward and 3.5 inches width rear. The steering gear is a worm and sector type that is irreversible, and is located at the left side. The ignition and fuel supply control levers are on the steering wheel and

speed changing and the emergency brake levers at the centre. The brakes are both external contracting, the service brake operating by pedal on the jackshaft and the emergency brake on the drums on the rear wheels. Because of the motor being under the driver's cab the wheelbase is 110 inches and the tread is 56 inches.

Two New Standard Types.

The Pierce-Arrow machines were of the standard type, there being no changes whatever in the constructions, but the two-ton chassis was exhibited for the first time in Boston, though it has been in the market for practically a year. The lighter chassis differs somewhat from the larger, the designs not being identical.

The Kelly exhibit included the new K-35 and the K-50 types, these being two and five-ton capacity machines, the older models being the one and three-ton sizes. But there is practically no variance in design, the difference being in the proportion of the

The Unit Power Plant of the Parcel Post Kar Assembled with the Rear Axle and So Installed That It Can Be Quickly Removed for Work When Necessary.

parts. The Kelly productions have been standardized in the fullest sense of the term.

Only Show Minor Improvements.

Aside from the increase of the size of the jackshaft of service brakes there has been no change in the Jeffery wagons, which are of 1500 and 2000 pounds capacity respectively.

The motors used in the 2500 and 4000 pounds capacity GMC wagons have been somewhat improved to minimize noise in operation, but the designs have not been varied from. The radiators have been changed from the honeycomb to tubular types, with the top and bottom tanks cast, so that the centre sections may be removed quickly in the event of needed repair. Other than this no variance has been made in the designs and the other sizes have been continued without change.

Parcel Post Kar a Novelty.

The Parcel Post Kar was the novelty of the show in that it is a construction differing widely from con-

The Power Plant of the Parcel Post Kar as Installed, Easily Accessible from the Sides or by Sliding the Body Forward.

ventional practise, and the design had evidently been developed with a view of meeting many requirements. Ease of operation and accessibility for work, so that one man could give any attention necessary, were the principal purposes in view. The power plant is located practically in the centre of the chassis, and it is so combined with the rear axle and wheels that the assembly can be removed from the frame body and forward construction in a comparatively short time. The body is forward of the driver, and the driving seat will contain two, it having the general characteristics of the small runabout body. The machine comes within the "light car" classification, but it has normal wheel-base and a slightly narrower tread.

The Parcel Post Kar has a wheelbase of 90 inches and tread of 52, and is equipped with wire wheels, 30 inches diameter, shod with pneumatic tires. The frame is tube and is underslung, being carried on two long semi-elliptic springs forward and a full elliptic spring mounted transversely above the rear axle. The forward half of the frame is given over to a box or compartment that is normally 56 inches length, 27 inches width and 18 inches depth. This box is so installed that it may be drawn from the chassis with a moment's work, and it may be carried forward whatever space is necessary to work on the motor, if this cannot be conveniently done through the doors at either side of the body.

Back of the box is the engine compartment. The motor may be either a twin-cylinder vertical type with the cylinders at an angle of 45 degrees, of the usual motorcycle construction, having bore of 3.5 inches and stroke of 3.5625 inches, and cooled by air, or a water-cooled, four-cylinder block motor with bore of 2.5 inches and stroke of four inches. The two-cylinder motor is rated at 10-12 horsepower and the four-cylinder at 12-14 horsepower. The description, aside from the engine, may be applied to either type of machine.

Unique Power Plant Assembly.

The power plant and power transmission assembly consists of the motor and a multiple disc clutch that is operated in oil, a transmission gearset of the

conventional sliding gear construction, affording three forward speed ratios and reverse, and the rear axle. The main driving shaft of the gearset carries a sprocket instead of a pinion, and a roller chain transmits the power to a sprocket incorporated with the differential assembly in the rear axle. This chain is driven in a bath of oil. From the motor to the rear axle the housing is continuous, and none of the working parts are exposed. This assembly is carried on a ball trunnion at the centre of a frame cross member, and it is supported by the two wheels at the rear, the body being mounted on the frame, which is suspended on the transverse full elliptic spring. The construction is such that by releasing the forward trunnion and the engine connections at the front end and the spring at the rear, the body and frame may be lifted and the chassis moved forward and the engine supported on two legs or standards for convenient work.

The rear axle is the usual live type, the wheels being keyed to the driving shafts. The shafts are mounted on Hyatt roller bearings. The steering column is at the left side with the gear shifting and brake levers at the centre. The brake lever operates a band fitted with cork inserts that contract on a drum within the rear axle housing, this being the emergency or hand brake, and it is ratchet retained when set. When the lever is pushed to an extreme forward position it can be used to start the motor, which is connected by linkage with a shaft carrying a pair of ratchet arms that engage with a six-inch gear that in turn meshes with a pinion on the engine shaft. The quick backward movement of lever brings one of the arms into engagement with the gear, and a clutch is engaged when the pinion is forced into contact with a collar on the engine shaft. As the pinion is free, and is forced into engagement by its helical teeth contacting with the gear, it is automatically disengaged when the motor begins firing. The starting device is enclosed and thoroughly lubricated. The clutch pedal also serves a

The Two-Cylinder Vertical Air-Cooled Motor of the Parcel Post Kar Removed from the Chassis as a Unit.

two-fold purpose, the first movement disengaging the clutch, and pushing it further forward applies a brake to the transmission. On the steering column is the fuel supply lever. The ignition is by an Atwater Kent Unisparker. The fuel is carried in a tank on the dash in the engine compartment.

Buffalo Electric Foot Control.

The Buffalo electric chassis shown was fitted with a patented foot control, by which, when the service brake is applied and the controlled handle is unchanged, the machine, as the brake pressure is released, will gain speed proportionately to the degree the brake pedal has returned to its normal position, just as it would were the controller handle moved forward. With these machines there are five forward speeds and these are obtained in order by pushing the controller handle forward. When in the fifth position, at top speed, and the service brake is applied and the machine stopped, without movement of the controller, the vehicle will continue stopped so long as the brake pressure is maintained. As the brake is released the vehicle will accelerate in precisely the same manner as though the controller were operated, and in the same ratios, so there is no possibility of a quick start being made that might be dangerous, no matter what the condition of operation. Aside from this feature the machines are unchanged.

Splendid Display of Body Work.

There was much attention given to body construction by the manufacturers, and what was undoubtedly the best exhibition of special equipment ever seen in any show made bodies really a feature. The White company's display was unusually diversified, this including practically every type that might be regarded as standard, as well as numerous special designs. These ranged from the 1500-pound wagon with highly ornamented panel body to the five-ton truck fitted with power hoist, and from the patrol wagon to the fully equipped combination hose and chemical fire wagon. The White display of specially finished bodies was especially attractive. The Packard exhibit was large and was generally made up of chassis equipped with bodies in general demand, these being of the express and dumping types as a rule.

The stand of the General Motors Truck Company contained both gasoline and electric machines, these being some fine examples of standard body work, but the interest was centred in a machine built for the Animated Advertising Company, which was one of a number, both gasoline and electric, that will be equipped for use in different sections of the country. The electric vehicles will be used in the cities, and the gasoline outfits will be sent over long distances, one of these being intended for a trip from Boston to San Francisco. These machines have enclosed bodies with glass sides and ends that are painted with different designs, but a portion of each side and end is made opaque. Within the bodies are installed electric storage batteries that actuate mechanism, and on the opaque glass colored pictures are shown in motion.

These vehicles are to be driven through the streets, the painted signs to serve by day, but at night the bodies are to be illuminated and the pictures shown. The first order is for a dozen machines, which will be sent wherever they can be used advantageously.

The Autocar Company showed a large number of standard chassis, each fitted with a body designed for a special service, and one of these machines was equipped with the smallest dumping installation exhibited. A number of these were delivered to Boston and suburban purchasers directly following the show.

The showing of fire apparatus was confined to exhibits by the White company, which was a remarkably handsome apparatus, a Knox-Martin tractor coupled to a converted horse steam fire pump, and an I. H. C. wagon that was designed specially for village use, it being light and yet carrying sufficient equipment to combat fire in the average residence.

The only exhibition of trailers was made by the Knox Automobile Company, which showed several Knox-Martin tractors equipped for general heavy haulage. These machines were of the standard type and no details of construction have been changed. At the Locomobile stand was shown a truck fitted with a McGarry body, which was attached to a dead wagon, and was intended for use in hauling or handling lumber.

The Garford company's agent exhibited one of its standard six-ton truck chassis equipped with the regular dumping body and power hoist specialized by this concern, as well as a number of truck chassis, some with platform and express bodies, and the Willys Utility wagon chassis, both with and without equipment.

The exhibit of the Buick Motor Company included a number of panel and screen express and open bodies, as well as a stripped chassis. One of the machines was noticeable for the load of ladders on it.

The KisselKar branch showed several completed chassis and several others with standard bodies. There was a very attractive showing of the four sizes of Lauth-Juergens trucks made by the New England agent, and these were all fitted with standard bodies. A three-ton Mais chassis was displayed by the United States Mill Supply Company, which has the New England agency for this machine, and which is to open a branch at Boston that will be operated in conjunction with its headquarters at Providence.

The showing of Reo two-ton machines was interesting because of the body constructions, while the Selden trucks exhibited were stated to be absolutely unchanged in any detail. One of the features of the Standard trucks displayed was the dumping body and power hoist, a chassis with this equipment being prominently located. The only steam machines shown were the Stanley, which were exhibited with panel and express bodies, and one chassis was fitted for passenger work.

The Kinney Manufacturing Company, Boston,

Mass., showed on a Peerless five-ton chassis is a 1200-gallon tank with equipment that adapted it for sprinkling or oiling streets, or applying tar of any consistency. The tank has a number of tube flues and a short stack at the forward end. At one side is carried a tank containing kerosene. At the rear of the tank is an asbestos-lined box containing two large plates, against which the kerosene is injected under pressure and forms a vapor that will ignite. When the plates become heated the kerosene vapor becomes gas that burns with intense heat. This is carried through the tank and heats the contents to any point, the temperature being regulated to a thermometer. With this the tank may be used for applying any tar preparation, which may be carried any distance, and used at whatever consistency is desired. The contents of the tank are forced from it by a pressure pump operated by the motor, set for whatever pressure is desired, and so constructed that should the outlets be closed the pump will by-pass, this obviating possibility of damage. The outlets are in two sections and they may be carried to either side to avoid obstructions, crossings, or to cover the turning radius. The tank may be cleaned by injecting hot steam into it when desired, and prepared for use with oil or water, the pressure pump insuring a constant head and even distribution. A number of these machines have been sold to municipalities and they have been found to be exceedingly practical. The equipment is designed for installation on a number of standard makes of machines.

The accessory and supply exhibits were limited in number, they being confined principally to those that were practical for service vehicle equipment or use. One that attracted attention was the Avon airless tire, made by the American Tire Company, Avon, Mass., this being composed of layers of wool felt. The layers are retained in place by a composition that does not affect the resiliency of the shoe, and the tread is composed of a fiber facing that is claimed to resist water or oil, and is extremely enduring. The tire is maintained to be lighter than rubber, proof against puncture and will not saturate and become compact when used in water or mud.

The following were exhibitors of machines:

Atterbury—Mattapan Motor Car Company, Mattapan, Mass.
Autocar—Autocar Sales and Service Company, Boston, Mass.
Buffalo—Buffalo Electric Vehicle Company, Buffalo, N. Y.
Bulck—Bulck Motor Company, Boston, Mass.
Chase—Chase Motor Truck Company, Syracuse, N. Y.
Federal—Whitten-Gilmore Company, Boston, Mass.
GMC—General Motors Truck Company, Boston, Mass.
Garford—R. & L. Company, Boston, Mass.
I. H. C.—International Harvester Company, Somerville, Mass.
Jeffery—C. P. Rockwell, Inc., Boston, Mass.
Kelly—Kelly-Springfield Motor Truck Company, Somerville, Mass.
Kissel—Kissel Motor Car Company, Boston, Mass.
Knox—Knox Automobile Company, Boston, Mass.
Knox-Martin—Knox Automobile Company, Boston, Mass.
Lauth-Juergens—Abrams, Myer, Company, Cambridge, Mass.
Little Giant—Little Giant Truck Company of Boston, Boston, Mass.
Locomobile—Locomobile Company of America, Boston, Mass.
Main—United States Mill Supply Company, Providence, R. I.
Merz—Merz Cyclecar Company, Indianapolis, Ind.

Packard—Packard Motor Car Company of Boston, Boston, Mass.
Palmer-Moore—Palmer-Moore Company, Syracuse, N. Y.
Parcel Post—Parcel Post Equipment Company, Cambridge, Mass.
Republie—Alma Motor Truck Company, Alma, Mich.
Reo—Linscott Motor Company, Boston, Mass.
Selden—Boston Motor Company, Boston, Mass.
Stewart—Maddocks, H. Ross, Company, Boston, Mass.
Standard—Whitten-Gilmore Company, Boston, Mass.
Stanley—Stanley Motor Carriage Company, Newton, Mass.
Universal—Magill, W. F., Boston, Mass.
Velle—Velle Motor Vehicle Company, Cambridge, Mass.
Walter—Walter Motor Truck Company, New York, N. Y.
White—White Company, Boston, Mass.
Willys Utility—R. & L. Company, Boston, Mass.

BOOMING ITS MEMBERSHIP.

Electric Vehicle Association Endeavoring to Increase to 1000 Members.

The membership committee of the Electric Vehicle Association of America, of which Joseph F. Becker is chairman, is making a vigorous campaign to increase the total of members from 560, which it now has, to 1000 before the annual convention in October. The committee in this work has sought the co-operation of all the members and has requested each to make a personal endeavor to secure one application at least, assuring them of any assistance that can consistently be given in this work.

The committee has undertaken this work systematically, first obtaining from every member of record confirmation of his name, address and other essential data, this insuring communication with them on all subjects of interest, and that all facts of importance relative to organization are placed before them. The committee is also obtaining from the members opinions as to the benefits derived from membership and whether or not they are receiving all the advantages that are practical or possible, and inviting suggestions as to what might be done to enhance the benefits.

The committee points out the fact that the officers and the members of the committees need co-operative help, the individual endeavors of members, to bring about activities that will have greater scope and be more productive, and develop the association on healthy and constructive lines. The members are urged to assist to the extent of securing the application of one new member, and sending the names of five prospects for the committee to endeavor to interest. The committee has prepared some interesting promotional literature, which emphasizes the advantages of membership in the association, pointing out the extremely broad scope of its endeavors wherever electricity is used.

The association now has branches or sections in New York, Boston, Chicago and Philadelphia, and promotion of additional branches in southern California and the extreme Northwest, which are expected to fructify within a comparatively short time, is now in progress. The association has increased materially since the Chicago convention, and the applications are coming in steadily.

MOTOR TRUCKS OF AMERICA.

"Motor Trucks of America" is the title of an unusually handsome volume of 112 pages published by the B. F. Goodrich Company, Akron, O., which might be expressed as being a tabloid autobiography of 95 different makes of machines, these being given in brief uniform specifications of each type produced. This volume is the second of the kind published by the Goodrich company, the first being issued a year ago, and the demand for it was so great that decision to continue it as an annual feature was reached.

The statement is made that the purpose originally was to show a number of representative motor trucks that were equipped with Goodrich wireless solid tires, affording information that is not generally supplied to the public, and to illustrate some of the types that might be considered standards in the market. Because of the requests made and the desire of manufacturers to be represented the second volume was materially increased in size. There is one illustration of each make of machine and the specifications are systematized and arranged so that much useful information is presented in brief form.

The book is cross-indexed so as to give both names of the trucks and the manufacturers, and contains an article by W. J. McDermid on "Efficiency in Buying and Operating Motor Trucks", which was first printed in the Review of Reviews, and an "Efficiency Guide for Buying Commercial Motor Cars", both of which are of special interest to the person using or considering the use of freight vehicles. The book is not distributed broadcast, but a copy can be secured at request addressed to the truck tire department of the B. F. Goodrich Company, made on the business stationery of responsible persons.

BAKER ELECTRIC SALES COMPANY.

The Baker Electric Sales Company has been incorporated at Chicago, Ill., and it is to be a direct factory branch of the Baker Motor Vehicle Company, Cleveland, O., and will market the Baker pleasure and freight vehicles in that city and vicinity. The branch will be under the management of Richard S. Greifen, who will be assisted by W. E. Henn.

The Autocar Sales & Service Company, Baltimore, Md., a branch of the Autocar Company, Ardmore, Penn., is now located in a new building in Cathedral street, removal being made from temporary quarters at 1010 Morton street, which were occupied after the destruction of the company's station by fire Feb. 20.

H. L. Smith, who is well known in the industry and trade, has been made manager of the St. Louis branch of the Kelly-Springfield Tire Company, succeeding John D. Lindsay, who recently died.

CONTRACT MAIL SERVICE.

The contractors for carrying mail between different postoffices, branch offices and railroad terminals and piers have, since the establishment of the parcel post service, been forced to extremes at times to do the work required of them with the equipment available, because of the unexpected increase in volume of sacks, for this is the measure by which the mail carrying is gauged. The contractors have to make their trips between points on schedule, and delay means penalization unless the cause is beyond their control. In small towns and villages the mail haulage has increased very largely, but the conditions are vastly worse in the larger cities, where accumulations are frequent because of the retardations of the trains.

Not infrequently a driver will be forced to carry additional sacks, although normally the government requires that all the sacks be locked in a body so that there can be no possibility of theft, and covered so as

Studebaker Panel Body Delivery Wagon Used by a Mail Contractor at Detroit, Mich.

to prevent damage from rain, and in such exigencies the resources of the clerks in charge of the work are severely taxed. An instance of what may result is shown in the accompanying illustration, which is that of a Studebaker delivery wagon used by O. H. Baldwin, a Detroit contractor, where after the body was filled the sacks of mail were piled on the roof, the running boards, the seat and the fenders and motor hood. Obviously the need was a larger vehicle, but as the contractors are expected to do their work for a stated price they necessarily use what will be the most serviceable the greater part of the time and meet emergencies when they arise as best they can.

The Y. R. Del Valle Company, Los Angeles, Cal., agent for Koehler 2000-pound delivery wagons, is finding a very ready sale for chassis equipped with bodies seating 12 persons, and has placed a considerable number of these machines in that city and vicinity.

WORK TRUCKS CONSTANTLY.

Garford Machines Operated 22.5 Hours Daily in New York Aqueduct Building.

Working 22.5 hours daily, Garford 6.5-ton trucks in the service of the Pittsburg Contracting Company, which is building one of the sections of the great tunnel that is to bring a supply of water from the Catskill mountains to the Metropolis, are doing each day as much haulage as could be accomplished by 30 two-horse carts. This appears to be an enormous volume of work, but not only is it possible, but it is done constantly. Of course the conditions are favorable, for the machines are seldom idle for a moment. In fact they are stopped only for half-hour periods for the crews to eat a lunch, and are taken by the one crew after the other, the men working in eight-hour shifts through the day.

The contractor regards the trucks merely as so much machinery that can be operated as nearly as possible to capacity, and aside from such attention as will keep them to the highest efficiency the main purpose is to keep them moving. The company is working in what is known as the down-town section of the city and the material is taken from the tunnel at several shafts and carried to a dump at 129th street, near the Hudson river. To complete the work within the period allowed a specified progress must be made daily, and the excavated material must be taken away as quickly as is practicable, for any accumulation would impede the workers.

Each truck has capacity of 6.5 tons, and each trip is made drawing a trailer that will carry a like volume of material, so that each haul a total of 13 tons is drawn. The loading is done from large hoisting buckets and the discharging is by gravity, so that the greater part of the time the machines are moving between the shafts and the dumps. The shifts begin work at 8 in the morning, 4 in the afternoon and at midnight, and aside from the replenishment of fuel and oil nothing is done on the trucks save during the half-hour allowed for lunch, when garage mechanics go over them carefully and make whatever adjustments are necessary.

Thus the machines are inspected three times daily, and any condition that is developed is ascertained. Despite the fact that the trucks are worked practically three times as much as the average vehicle, this close supervision keeps them constantly operative, and thus far no time has been lost. Apparently the work can be continued with this system for an indefinite period. Obviously, the saving that is made is very large, for the average price for a two-horse cart and driver in New York City is practically \$6 a day, and a day's work would be 10 hours, normally. Considering the difference in the working time the trucks are each doing in 24 hours work that would require 24 two-horse carts, each working 10 hours daily.

EXCLUSIVE TRUCK GARAGE.

A garage designed for the exclusive accommodation of the users of motor trucks and wagons, and to afford service to the owners of large transportation equipments who now maintain independent garages or store their vehicles in combination stations, is planned for Cleveland, O., and is to be erected in Carnegie avenue. The plan comprehends a structure 75 by 570 feet with a rear wing 95 feet width, with a two-story head house and a single-story structure back of this, which will be lighted by a saw-tooth roof. The building is to be of concrete and steel, fireproof, and the cost will be about \$125,000 with the equipment. The garage will be equipped for the storage of both electric and gasoline vehicles. Statement is made that a number of department stores and other large users of machines have assured their patronage, they expecting to obtain more economical as well as specialized service. In connection with the garage will be a salesroom and there will be a sales department maintained by the company operating it.

LICENSING BILL ABANDONED.

A bill before the New York legislature which provided for the licensing of all drivers of motor vehicles, whether owners or servants, was abandoned at a hearing held at Albany, March 11. The bill provided that every owner should be examined, that his photograph should be attached to the license to insure identification, and that while driving a badge should be displayed prominently on his outer clothing.

General Sales Manager W. H. Moore of the Gramm-Bernstein Company, Lima, O., started April 1 on his annual visit to the agencies of the company, starting for the southern states. Mr. Moore expects that the business of the company in the South will be materially increased the coming season.

The Kissel Motor Car Company, Hartford, Wis., has just published a book that contains more than 350 illustrations of KisselKar trucks and wagons now in service. This book is very interesting and demonstrates the greatly diversified uses that may be made of these machines.

Because impaired health impelled a long rest and relaxation from business, C. E. Mathewson, for 12 years western representative of the Diamond Rubber Company, resigned that position March 21 and began preparations for a journey that will take him round the world.

With capital of \$830,000 the Salom Electric Storage Battery Company has been incorporated by H. E. Latter, W. J. Mahoney and O. J. Reichard, all of Wilmington, Del., with authority to manufacture storage batteries and electric apparatus and appliances.

BUSINESS EXPANSION FROM MOTOR TRUCKS.

Remarkable Increase of Retail Trade, by Routes and Stores in Boston and Vicinity, by Hood & Sons, New England's Largest Independent Dairy Company.

BUSINESS development through the utilization of motor vehicle haulage equipment has been the ideal of every power wagon or truck salesman. The subject has been so frequently presented to business men that at least a majority believe they are fully conversant with it. Any suggestion of possibilities seldom has full significance, because of supposition that theory, and not practise, is the basis. Or, to put it another way, the value of the phrase has been lost because of its constant and very general use.

For this reason the term business expansion has been substituted, and that there shall be no misunderstanding this has been applied to increase of transactions that could not be realized in any other manner than by the service of motor vehicles. The statement that a dairy business has been expanded to several times its proportions within approximately three years, because motor wagons and trucks were utilized for transporting, may appear to be extravagant use of language, or at least an enthusiastic presentation of the subject, particularly when the qualification is made that a very small part of the delivery is made directly by machines.

Yet there is probably no better illustration of the possibilities of efficient highway transportation than the business of H. P. Hood & Sons, which is claimed to be the largest independent dairy company in New England. The concern has headquarters at 494 Rutherford avenue, Boston, this being in the Charles-

town district, close to the freight yard of the Boston & Maine railroad, and it has branches as well as stores in Boston and its suburbs, besides commercial connections in a number of the principal cities.

The company is not a contractor in the sense that is usually applied to those dealing in milk. It is a producer and a distributor, and while it purchases milk in large quantities for its own customers, it may be regarded as a retailer. The contractors are those who purchase milk by contract with the producers, having stations to which this is shipped, and in turn delivering it to those who retail it, the contractor being practically the jobber or middleman.

The contractor and jobber have business relations with the producers who supply them to the extent of

furnishing cars which are hauled by different railroads and the milk is delivered at the stations in season for shipping, so that one or a number of cars may be attached to a train, and a considerable number may arrive within a stated period at a terminal. The contractors may deliver milk in large quantities to customers, or it may be hauled by them, so that in the majority of instances when it has been received and turned over to the buyers the problem of distribution is for others to solve.

Milk is a distinctly perishable commodity and susceptible to contamination, and much care is taken to see that it reaches the market in condition to use as food. Milk purity is regarded as the greatest quality that can be stated, and volume of business and price are entirely dependent upon it. The Hood & Sons business has been established for a long time, but its growth was to a large degree dictated by the means of

Also Truck of 6.5 Tons Capacity with the Big Body Built for Haulage of Bottled Milk in Cases—The Largest Machine of the Equipment.

transportation that would justify the firm in attempting to serve communities. The reason was that the concern has sought to establish its products as specialized, and wherever sold the name of the firm has been identified by the public as being linked with quality.

Does a New England Business.

Hood & Sons owns a farm of 1000 acres at Derry, N. H., which has on it upwards of 350 head of stock, the cows being of breed that produce milk of a required standard. In addition to this source, milk is obtained from other producers in New Hampshire and Massachusetts. The company originally dealt only in milk and cream. But it now does an extensive business in butter, cheese, buttermilk, condensed milk and eggs.

Autocar with the Special Crate Body Adapted for Carrying Cases of Bottled Milk—Six of These Machines Are in Regular Service, Two of Them for Special Delivery.

The main station is at Rutherford avenue, but it has branch stations at Forest Hills and South Boston in Boston, at Lynn, Salem, Chelsea, Medford, Malden, Brookline and Bemis, and in Manchester, N. H.; Nashua, N. H., and Lawrence, Mass., and it has 20 branch stores in Boston besides the central office or principal store in South Market street. In addition to these places of business directly under its own control it has numerous agents in other cities, and its products can be obtained in practically all of New England, from Manchester on the north to Springfield on the west, and Newport and New Bedford on the south.

Assumedly the reader will regard the business as wholesale from what has been stated, but when it is known that the company owns approximately 400 horses, with which delivery is made from the branches to families and similar customers by more than 325 different routes, the volume of the retail custom can be understood. With this number of animals and the 325 milk routes to be served every day of the year, the value of the motor wagons and trucks may not appear clear, but without them the business could never have obtained its present proportions, and it would not be practical to undertake distribution of anything like the quantity of milk.

To understand the situation clearly a word of explanation is necessary relative to the railroad facilities. Boston is south of the Charles river, save the Charlestown and East Boston districts. The Boston & Maine railroad enters the city to the North station, but the freight yards are in Charlestown. The Fitchburg and other railroad properties merged with the Boston & Maine use the same passenger

terminal, and the freight yards are in Charlestown. The New Haven railroad and its allied property enters the South station from the south and southwest. The freight yards are along Albany street, and the Boston & Albany railroad, now controlled by the New York Central, which enters from the west, uses the same terminal. Thus the railroad services that use the same terminals are separated from each other by the Charles river and by the business districts of Boston, and it is impossible to make transfer of cars from one system to the other within a

reasonable distance of the city.

The Boston & Maine railroad controls the railroad traffic from the northern part of Massachusetts and Maine, New Hampshire and Vermont, while the others similarly control traffic in the remainder of Massachusetts, Rhode Island and Connecticut. But at Boston the freight terminals are separated. For this reason the firms dealing extensively in milk—and the Derry farm is the cogent reason with Hood & Sons—located as closely to the railroad terminal in Charlestown as was practical. This situation being understood it will be evident that all products received at this Charlestown plant of the company must be sent across the river to serve Boston, Brookline and Bemis, and to the cities of Chelsea, Malden, Lynn and Salem and the town of Medford at the north. Manchester, Nashua and Lawrence are not served from Boston and have for the time being no connection with the distribution with which this article deals.

Main Plant at Charlestown.

The main plant of the concern extends back from Rutherford avenue to the Boston & Maine freight

Some of the Machines at the Garage, a Two-Ton Truck in the Entrance, a 6.5 and a Five-Ton Truck at the Curb and the Autocar Wagon in the Court.

yard, and there are sidings on which the cars containing the milk are stationed for unloading and loading with the containers. The main building, in which the milk is received and prepared for distribution, extends along one side of a court or yard, and at the side of this building is a long shipping platform. The court is paved and is of such width that any vehicle can be turned without backing. As may be assumed the milk, cream, buttermilk, etc., is not hauled at the plant, the facilities being adapted for minimizing handling, but unless sent to customers who use it for manufacturing purposes it is always placed in bottles and these are of different sizes. The bottles are placed in racks for convenience in handling, these being of wood and divided into compartments of the size required.

Care to Maintain Quality.

The firm has devoted its endeavors to educating the people to the quality of its products, and has established a reputation that has made a demand that had been quite beyond the capacity of its organization to supply. The Hood milk has been obtained in conditions where extreme caution was taken to insure purity. The milk, wherever it is produced, is brought to Charlestown, and at the plant has been prepared for distribution. The dairying at the farms has been with every care that practical science could suggest. Were the milk sent to different plants it would not be possible to handle it as uniformly and with the methods that have been developed, and for that reason the centralization of the receiving and preparation has been productive of excellent results.

The firm prides itself on the general excellence of its plant and its organization. Seldom a day passes that large numbers of visitors are not received at the station, where every process of preparing the milk for distribution is demonstrated. As a rule the visitors are women. The company employs a physician, whose duty is to educate the people to the value of dairy products for food and to interest them in the Hood methods. He is constantly in contact with women's organizations, advising them of home hygiene and of means by which health can be preserved by care in preparation of foods in which dairy products are used, and he exercises a supervision over the plant, the branches, the stores and the distribution.

Because of the perishable character of milk and the necessity of hauling it long distances, great care is taken to keep it at low temperatures. Milk will not deteriorate so long as it is kept chilled. After cooling at the farms it is delivered to cars that are iced in

the warm period of the year and brought to Charlestown, where it is transferred to storage rooms and removed to the bottling department as needed. Because of the large quantity handled this work must be done according to schedule. Cars arrive at different times, day and night, and as the milk is received and made ready it must be distributed.

Retail Distribution by 325 Routes.

Each night at 1 o'clock from the different stations of the firm the route teams leave to serve their customers, for custom has decreed that milk must be delivered in season for breakfast if possible, and the greater part of the delivery is made before breakfast, and practically all of it by the middle of the forenoon. At Charlestown practically 100 route wagons are loaded, and in the three stables of the firm close to the plant are about 130 horses. At Forest Hills, which is a centre for the suburban portion of Boston, there is a branch that has a stable with 75 horses and about 65 routes are served from this station. At South Boston

Looking into the Yard of the Main Plant from Rutherford Avenue, Showing a Part of Its Depth, with the Long Loading Platform at the Right.

the branch has a stable with 25 to 30 horses and about 25 routes centre there. The Lynn branch serves upwards of 30 routes, the stable having 35 horses; the Salem branch has 15 routes and 18 horses, the Chelsea branch 15 routes and 17 horses, the Malden branch 15 routes and 17 horses, and Medford, Brookline and Bemis have each 10 routes and 12 animals. At Manchester the branch stable has 16 horses and 14 routes are served, at Nashua the stable contains 12 animals that are used on 10 routes, and at Lawrence there are nine horses and eight routes.

In the different sections of Boston the firm has 20 stores that are stocked with milk, cream, buttermilk, butter, cheese and eggs, and there are large concerns, such as the store of the Houghton & Dutton Company, that are supplied considerable quantities of all classes of stock. The stores are opened early in the morning and each must have whatever supplies of milk, cream and buttermilk are needed, but the other products can be replenished at less frequent in-

Closer View of the Loading Platform. Showing Some of the Trucks, Filled with Cases of Bottled Milk, Preparatory for the Start for the Branch Stations.

tervals. Previous to three years ago the company had branches at Forest Hills, Malden and Chelsea, and the supplies for these stations were hauled by animal vehicles from Charlestown. Since that time the other branches have been established, and the chain of stores in Boston developed, as well as customers served who could not previously be dealt with.

Motor Equipment of 19 Machines.

Nine years ago the company purchased a Knox truck and with this served a route of customers at Nantasket Beach, but conditions were not favorable at that time and after an experience covering one summer this section was abandoned. Three years ago the company purchased its first machines and it now has in regular use eight Alco trucks, one of 6.5 tons, two of five tons, three of four tons, one of three and one of two tons capacity, and six Autocar wagons with load rating of 3000 pounds each. Two small vehicles that were bought four years ago and have been used in delivery were found to be too light and have been withdrawn from general service and are retained as spares. In addition there are three pleasure cars that are used by the general manager, the company's physician and the manager of the motor vehicle department.

The use made of the trucks and the Autocars is much more continuous than in ordinary service. The trucks are moving from 17 to 21 hours a day, and as milk is delivered to all of the stations seven days in the week, it will be understood that the mileage continues Sundays, although not as large as business days. The company, about the middle of December, 1913, occupied a fine fireproof concrete garage that was built at 527 Rutherford avenue, but until then, because of the almost constant use made of the machines, they were seldom housed, but three of them were kept at Somerville, and the others were sheltered in whatever place was convenient.

From the Charlestown station the distances to the branches are as follows: Forest Hills, eight miles; Lynn, 10 miles; Salem, 17 miles; Bemis, nine miles; Brookline, six miles; Medford, five miles; South Bos-

ton, Malden and Chelsea, four miles.

Considering these for a moment, it will be seen that with the original branches at Forest Hills, Malden and Chelsea, the hauls were eight miles for the first, and four miles for each of the other two. To supply Forest Hills branch it was necessary to use four four-horse wagons, each carrying a load weighing from six to seven tons, and to haul the Malden branch stock one four-horse wagon and one two-horse wagon were required, the load averaging about eight

tons. A round trip to Forest Hills was a day's work for a horse team, and because of the conditions the horses making the Malden haul could do other work. But as the time in which the work could be done was limited no economy could be made in the number of horses and wagons used.

The distribution of milk in bottles from the plant to the branches or from the branches to the retail customers means that following a full delivery the return is made with about 60 per cent. of the weight, for the cases and the empty bottles collected or handled will average about that proportion. This applies to the route deliveries as well. Not including the routes served from the Charlestown plant, the stores, or the wholesale customers, and considering only the branch business, approximately the following tonnage is hauled by the trucks and the Autocar wagons: Forest Hills, 25; South Boston, 19; Brookline, 10; Malden, 12; Medford, nine; Chelsea, 13; Lynn, four; Salem, 1.5. This statement does include the Bemis branch, but shows that the haulage to the stations specified is approximately 92 tons.

Branch Service of Vital Import.

Time is an important factor, for the distribution is begun each morning at 1 o'clock, and for this reason, and to have the milk as fresh as possible, bottling is begun as the cars are received and it is continued through the day and evening. The trucks are started on the first trips to the branches at 4 in the afternoon, and they are worked until about 2 o'clock in the morning freighting to the branches, the last trips carrying products for the latest department route wagons.

This work is distributed in part in the following manner: To Forest Hills, one five-ton truck makes three trips and the 6.5-ton truck one trip, while the last load is taken by a machine that will carry whatever is required, this being either a four, five or the 6.5-ton machine. The 6.5-ton truck makes three trips to South Boston. A five-ton truck makes two trips to Brookline. A four-ton truck makes three trips to Malden. A five-ton truck makes three trips to Chel-

sea. A 3.5-ton truck makes three trips to Medford. The work to the other branches is somewhat dependent upon requirements. Autocar wagons are stationed at Lynn, at Salem and at Forest Hills, and a fourth is used in serving the South Market street store in Boston, and two other Autocars are used for special deliveries and general emergency work. The Salem machine comes to Charlestown each night and hauls the supply over the road, and that from Lynn comes to the plant an average of four times a week, for about four tons freight is sent to Lynn daily.

Freight Haulage Besides Delivery.

But in addition to the direct branch haulage the machines are required to make deliveries to the stores, to the wholesale customers, to deliver, in addition to the cases of bottled milk, cream and buttermilk, the butter, cheese, eggs and condensed milk, and to do freighting of hay and grain and supplies of all kinds. To illustrate, the five-ton truck in the regular Forest Hills branch service makes an average of 72 miles daily, one man driving it to Forest Hills, and another taking it for the freight work. The 6.5-ton truck serving South Boston is driven 40 miles a day. The five-ton truck doing the Brookline haulage also makes one or more trips to the milk bottle exchange and has one or more loads in this work, averaging 32 miles a day. The four-ton machine hauling to Malden is worked with a double shift, the second man driving it 26 miles on two wholesale routes and a North station trip, the total work being about 51 miles daily. The 3.5-ton truck worked between the plant and the Medford station makes four trips to the company's stores and in addition is worked on freight and wholesale trips, this having a total mileage of 58 miles, and the five-ton truck serving the Chelsea station is worked an average of 70 miles a day, of which but 24 is between the plant and the branch. One three-ton truck is ordinarily used for general work, not having a regular assignment, but this is driven about 25 miles a day in ordinary service.

The Autocar attached to the Salem branch is driven 60 miles a day, that machine at Lynn is worked 40 miles, that at Forest Hills 35 miles, and that at the South Market street store 40 miles, and the other two in special delivery vary from 50 to 75 miles, according to the requirements. When circumstances have required machines have been worked continuously for 24 hours with three shifts of men, and seven days a week. Sunday is the day of least work of the week, for there are no company stores or wholesale customers to serve, freights are not carried and

the bottle exchange is not open, but the distribution of milk to families must be made from the branches, and the demand is always heavier Monday because of the diminished supply from the Sunday consumption. In addition to this the Monday distribution is large because of the general replenishment of the stocks of the stores, and the greater general demand.

All the additional work must be done by the trucks. The reason for this is obvious. The branches are supplied with whatever is required to meet demands, but stock must be hauled from the Charlestown plant. Shipments cannot be made by railroad direct to the branches because of the conditions obtaining. Preparation of the products can be made more economically at Charlestown, but the branches must be located conveniently to the centres of patronage because of the route distribution, for which horses have been used, for a great deal depends upon the service that can be afforded, and the possibilities for competition must be considered.

Branches Dependent on Patronage.

It must be understood that a considerable volume of patronage is necessary to justify the location of a branch, and when established a great deal of attention is devoted to promotion and development of custom. There is a limitation to the time of delivery in the morning, and distribution cannot be begun too early, especially in the warm weather, because of the necessity of keeping the milk and cream cool. The volume of business increases with the spring and summer months, and the work is proportionate to this increase. Horses have been used for route distribution, as the stops are very frequent, the customers often close together, and as the bottles must be carried into the houses in many instances, or left where they are not exposed to theft, and the empty bottles must be collected, much of the work of the drivers is going to and from the wagons. The animals become educated to the work and many of them will follow a driver, or obey commands, so that delivery is facilitated, but a motor vehicle could only be used by re-

The Fireproof Concrete Garage Building, Completed Last December, and Planned for Expansion by Constructing Additional Stories.

turning to it after each delivery, starting the engine (if this had been stopped), and the short distances between stops are frequently such that there is a great deal of doubt as to the economy that is practical with them.

Use of Machines for Route Delivery.

The company is working out Autocar delivery at Salem, however, which will probably determine the possibilities very accurately. The first machine was placed in service in that city in 1912, this serving a route of shore customers, carrying a full load and making retail distribution. Last year a second machine was sent out to a second route, and this spring a third will be used, and from these the company expects to obtain some very definite facts. These routes, however, are much longer and are not comparable as a rule with those from the branches, for one of them will extend to Gloucester, which is a much longer distance than could be worked successfully with animals.

One possibility is that of serving a greater number of customers, because of the larger capacity of the machines, both as to load and mileage, as compared with horses, and by working two men on them instead of one, as is now the custom. The use of these machines the coming summer is expected to result in some very practical information. The routes as a rule are longer than those served by horses, and the loads carried are larger.

The actual work of the trucks is begun daily at 4 o'clock in the afternoon, when the first loads for the branches are taken out, and from that time until the next morning, and possibly until noon, the haulage is continued. As might be assumed, the volume of freight for a concern of the proportions of Hood & Sons is very large, and it is increasing constantly. The company trains its own drivers, preferring to take inexperienced men and teach them to employing those who have gained their experience in the service of others. Aside from replenishing the fuel, water and oil tanks, and oiling and greasing the exposed working parts, the drivers have no work on the machines. All else is done by the garage force, and the machines are constantly observed by the superintendent of the motor vehicle department.

Some Facts as to Operating Cost.

The garage is a model, of concrete and fireproof, and designed by the addition of one or more stories in the event of need. It is 42 by 112 feet, with two main entrances from Rutherford avenue, and the main floor is clear, the superintendent's office being between the entrances. At the rear is a repair shop, separated by a heavy wall and a fireproof door, and this is also accessible for vehicles by a rear door. The shop has an equipment of floor crane and machine and hand tools to make practically all repairs, and there is a stock room where a supply of spare parts and material is always available. Spare wheels for the trucks and wagons, with and without tires, are ready for use when needed, and should a machine be delayed from failure or breakage, the driver telephones

the garage and men are sent who will make a repair. If repair is impossible another machine is sent to take the load. As care is taken to have the machines in good condition at all times they are seldom delayed from any cause, and not for two and a half years has a vehicle been towed in. Daily inspection means a great deal and does much to minimize maintenance.

Because of the work that each machine does the cost of operation is relatively smaller, for the reason that the fixed charges are not increased with additional mileage, and the operating expenses are not doubled, these being the items of wages, fuel, lubricants and repairs; but the overhead expense, the depreciation, taxes, interest, insurance, storage, etc., are not increased. The operating cost is kept, this including gasoline, oil, repairs (which include all labor), parts and tires, and to this is added each driver's wage. The machines are washed and cleaned daily and are extremely well kept, despite the continuous service. The depreciation is computed on a three-year basis. The work done by each machine is recorded and the cost is established, this being slightly in excess of the operating expense, but no attempt is made to compare the same service with the cost of animal haulage, for a good part of this would not be practical.

Last summer an experiment was tried for a month, that of sending the 6.5-ton truck to Lawrence daily, but this was not continued because it was not believed that the work was as economical as other service for which the machine was available. The truck hauled a load averaging seven tons to Lawrence, and returned with a load of empty bottles. The haulage has been since that time considerably shorter distances, Salem being the longest trip that is made up to the present time.

CITIZENS' TRAFFIC COMMITTEE.

The Citizens' Street Traffic Committee of Greater New York has been permanently organized by the election of the following officers: President, Robert Grier Cook, Fifth Avenue Association; treasurer, G. H. Pride, Motor Truck Club of America; secretary, Elmer Thompson, Automobile Club of America; executive committee, the three officers named and R. W. Meade of the Fifth Avenue Coach Company and S. W. Taylor of the Uniform Motor Vehicle Legislative Commission. A petition has been presented to Mayor Mitchell and Police Commissioner McKay asking that a deputy police commissioner be appointed to have direction of the regulation of street traffic. The organization as completed is to continue for one year and the committee will meet every alternate week in regular session. As stated, the purpose of the committee is to assist the police department in every way that will bring about improved conditions.

The statement is made that the Rutenber Motor Company, maker of motor vehicle engines, is to establish a branch plant at Berlin, Ont.

TWO NEW WATER-COOLED CHASE TRUCKS.

THE Chase Motor Truck Company, Syracuse, N. Y., which has for years built light weight motor vehicles of the wagon type, using large wheels and small tires, with three-cylinder, two-cycle, air-cooled motors as standard power plants, has, because of the demand for machines which will carry heavier loads, and have lower centres of gravity, and for engines that are regarded as more conventional, added to its production two machines of 3000 and 6000 pounds capacity. The Chase company will, however, continue to produce the standard types such as it has built for seven years in the smaller sizes of vehicles, and will build the new models in such numbers as may be required to meet the demands of those who desire its machines.

The smaller of the two is built in two chassis lengths, 146 and 160 inches, the longer being produced only to order and the shorter being the standard stock model. The tread is 58 inches. The motor is a Continental model C, a four-cylinder, water-cooled, L head type with the cylinders cast en bloc, having cylinder bore of 4.125 inches and stroke of 5.125 inches. This engine has an S. A. E. rating of 27.2 horsepower, but is claimed by the maker to develop 30 horsepower under practically any condition of normal operation. The cooling is by a circulation of water through a radiator of generous proportions, and the lubrication is by a positive plunger pump system with constant level of oil in the crankcase, one lead of tube flooding the timing gears and another the rear main bearing, the other moving parts of the motor being lubricated by splash. The ignition is by a Bosch DU4 magneto with automatic spark advance. The engine is governed to 1250 revolutions a minute by a governor that is set and sealed at the factory and cannot be changed without the knowledge of the owner.

The clutch is a multiple disc type, and the transmission gearset is a three forward speed and reverse selective construction that is assembled with the jackshaft, the assembly being mounted on three points to avoid the stresses of chassis frame distortion. The gear ratios are designed to give speeds of 15.6, 8.5 and 4.5 miles an hour respectively in forward movement, and 3.5 miles an hour in reverse. The design of the gearset is such that but one driving gear may be engaged at any given time.

The chassis frame is a pressed steel channel section that is mounted on

semi-elliptic springs, the rear springs under-slung, the front axle being an I section and the rear axle a rectangular section. The wheels are 36 inches diameter, the forward wheels being shod with 36 by four-inch single tires and the rear wheels with 36 by three-inch dual tires. Both brakes are operated by pedal, the service brake having shoes expanding in drums on the rear wheels, and the emergency brake bands contracting on the same drums. The loading space of the standard chassis is 109.5 inches length and 48.5 inches width, and the length of the chassis is 205 inches. The machine is left side driven and the control levers are in the centre.

The three-ton machine is designated as model O and this is driven by worm and gear wheel, having a gearset that affords four forward speeds. The motor is also a Continental model E, this being a four-cylinder, water-cooled, L head construction with the cylinders cast in pairs. The cylinder bore is 4.5 inches and the stroke is 5.5 inches. The motor is given an S. A. E. rating of 32.2, but the maker claims that it will develop 40 horsepower in normal conditions of service. The engine is cooled by water circulated through the water jackets and a large radiator by a centrifugal pump, radiation being promoted by a belt-driven fan. The radiator is mounted on springs and may be quickly removed when necessary. The lubrication is a positive plunger pump and constant level splash system, the oil being drawn from a reservoir and supplied to the timing gears and rear main bearings, the overflow filling the pits into which the ends of the connecting rods sweep. The oil is circulated through a sight feed glass on the dash. The valve mechanism is enclosed to protect the working parts. The ignition is by a Bosch DU4 magneto fitted with automatic spark advance. The motor may be governed to any desired speed by a sealed governor. The dry plate clutch and

The Model O Three-Ton Chase Truck, This Having a Water-Cooled Motor and Being Driven by a Worm and Gear Wheel, There Being No Radius Rods.

the four-speed Brown-Lipe transmission gearset are assembled in a unit with the motor. The high speed ratio of the gearset will drive the machine 15 miles an hour. The direct drive is on the third ratio.

From the gearset the drive is through a propeller shaft in which are two universal joints, to the Sheldon designed rear axle, in which the worm and gear wheel are the David Brown type. This axle is constructed to carry 80 per cent. of the load and has a large margin of safety. The frame is a channel section of pressed steel having a width of 6.5 inches and depth of 5.5 inches, .25 inch thickness. This is well braced and has three cross members that insure ample strength. This is mounted on semi-elliptic springs, the rear set being underslung. The forward axle is an I section. The wheels are fitted with 36 by four-inch single tires forward and 36 by four-inch dual tires rear.

The drive is at the left side and the speed changing lever is at the centre. Both sets of brakes are pedal operated and act on rear wheel drums, the service brake shoes being of the internal expanding type, and the emergency brake bands external contracting.

The wheelbase is standard at 148 inches, but can be furnished when desired at 165 inches length. The tread is 62 inches. The standard chassis length is 218.5 inches and this allows a body with loading space 122.5 inches and width of 52 inches. The special chassis gives 20 inches additional length. As designed the chassis weight is equally distributed on the four wheels, but when loaded 20 per cent. of the freight is carried by the forward axle. When desired other gear ratios can be given the worm and gear wheel and higher or lower speed obtained.

MOTORISTS WANT GOOD OILING.

A five-ton Garford chassis, equipped with a 1000-gallon tank and apparatus for applying oil uniformly under pressure, has been ordered by the Automobile Club of St. Louis, Mo., and this will be given to St. Louis county with the understanding that the county shall operate it and oil the principal highways. The chassis will have the best equipment and is expected to be serviceable for a number of years. The club will spend \$10,000 in road oiling, and the purchase of the machine represents a considerable part of that sum.

MOTOR TRUCK PUBLIC SERVICE.

The plans for a public service that has been established between Mason and Brady, two Texas towns, are unusually ambitious, and if the proposition of the people of the town communities is realized a road with good surfacing will be built by McCulloch and Mason counties for the use of these and other motor vehicles. Passenger omnibuses are operated on schedule time between the towns, and shortly trucks will be used to give regular freighting service.

NOW THE MOTOKART COMPANY.

The MotoKart Company, with capital of \$500,000, has succeeded to the business of the Tarrytown Motor Car Company of Tarrytown, N. Y., with capital of \$250,000, and the Steinbock Engineering Company of Peekskill, N. Y., taking over the business of the two concerns March 2, the executive offices being continued at 1790 Broadway, New York City. The officers of the new company are announced as follows: President, A. R. Gormully; vice president, H. E. Steinbock; sales vice president, G. C. Wolfe; treasurer, B. J. Knerr; secretary, E. M. More; purchasing agent, F. C. Sievers.

Until the date stated the two plants were operated independently, the engines, transmission gearset, axles and other mechanical parts being built by contract by the Steinbock Engineering Company, and the frames, bodies, wheels and fenders being made at Tarrytown, where the vehicles were also assembled and painted. Both factories are now producing the same work as before, both being worked exclusively for MotoKart construction.

The MotoKart Company has planned a very aggressive publicity and selling campaign and it has systematized its manufacturing so as to meet a very general demand for its machines. The MotoKart wagons weigh 900 pounds and have capacity of 400 pounds. They are compactly built, with wheelbase of 69 inches and tread of 44 inches, this making for easy handling in all conditions of operation and requiring very small storage space. The company has issued a new catalogue in which are illustrated the box and open types of bodies with which the chassis are equipped, either of which is furnished at the same price. Copies will be sent to any person at request.

REPUBLIC TRUCKS IN DEMAND.

The business of the Alma Motor Truck Company, Alma, Mich., builder of Republic 2000-pound delivery wagons, has been excellent, and the prospect is exceedingly satisfactory, according to statements made at the annual meeting of the company. One probability is increasing the plant to afford sufficient facilities for production. Francis King was elected president, and E. W. Ruggles vice president and general manager.

PEERLESS OFFICERS ELECTED.

The stockholders of the Peerless Motor Car Company, Cleveland, O., at the annual meeting, elected the following officers: President, L. H. Kittredge; vice presidents, E. H. Parkhurst and Theodore C. Frech; treasurer, H. A. Tremaine; secretary, George B. Siddall. J. B. Crouse retired as vice president and F. S. Terry as director, their positions being filled by the election of Mr. Frech to both, but they have not relinquished their holdings of stock.

CO-OPERATIVE DELIVERY.

A plan of co-operative delivery has been inaugurated at Paxton, Ill., which will be worthy of the observation of those doing a small business that requires constant distribution to customers. A number of butchers and grocers of Paxton have made agreement with James Wolfe and David Johnson, who have purchased three motor delivery wagons and will undertake the delivery for these stores at a stated price on a package basis. The three trucks are expected to do more work than 10 single-horse wagons in a stated period of the day, and that there will be considerable economy resultant for each concern, as well as eliminating the responsibility to a large degree.

OPERATES 84 WHITE MACHINES.

With the acquisition of three 3000-pound White wagons recently the Atlantic Refining Company, which is the leading distributor of petroleum oil products in western Pennsylvania, now has 84 machines of that make and of different sizes in its service. The company has utilized machines for a considerable time and with the establishment of each new station uses one or more to make distribution, for the service afforded its customers has been a very practical reason why its business has been materially developed, and the deliveries have been extended over areas that could not be served with any other equipment.

EXPORT TRADE WITH RUSSIA.

The Russian trade division of the National Association of Manufacturers has organized a series of open meetings at the headquarters of the association at 30 Church street, New York City, with Hon. C. J. Medzikhovsky, commercial attache of the Russian embassy at Washington, for the purpose of fostering trade with Russia. The first of these, April 1, was devoted to the consideration of exportation of agricultural machinery, traction engines and heavy trucks, and that to be held April 23 will be given over to the prospects for exporting passenger cars. These meetings are intended to promote trade in numerous lines.

NEW FEDERAL VICE PRESIDENTS.

The board of directors of the Federal Motor Truck Company, Detroit, Mich., has elected Galvin B. Denby, secretary and treasurer of the company, and M. L. Puicher, its general manager, to be vice presidents. They will continue as such in the offices which they previously filled.

The Gramm-Bernstein Company, Lima, O., has just issued a new catalogue, which is descriptive of the four sizes of B. A. Gramm's trucks built by this concern.

ADVERTISING WITH MOTOR TRUCK.

Those using motor vehicles can consistently develop advertising possibilities with them at comparatively small expense, for in regular service the machines are generally driven many miles daily, passing within the observation of many people. As a matter of fact few motor wagon or truck owners realize what can be accomplished by carrying appropriate advertising signs on the machines. It is well enough known that a truck would not attract attention while passing through the streets unless carrying an unusual load, but as trifling an object as a flag or pennant would be noticed by hundreds, if not thousands.

For this reason signs that are comparatively inexpensive and can be changed frequently, of sufficient proportions to be easily read at a distance, can be used to material profit. Of course where appearance is valued there are those who depend upon the finish of the machine to attract observation, but where results and not permanent ornamentation are regarded the cheap sign that will be useful for several days, and can

Advertising Possibilities Developed by John D. King, Poughkeepsie, N. Y., Dealer in Motor Vehicle Supplies.

be replaced by another in a short time, will insure practical returns.

An instance of this character is the vehicle owned and used by John K. King of Poughkeepsie, N. Y., who is a dealer in motor vehicle supplies. He specializes in what he knows will interest owners and drivers of wagons and trucks and has become known in a business way to practically all residents of the city in which he is located. This form of publicity is legitimate and has been very productive.

In the list of specifications of electric vehicles published in the March issue of **MOTOR TRUCK**, a typographical error caused the price of the five-ton chassis built by the Commercial Truck Company of America to be stated as \$9535, when the correct price is \$3935.

Work has begun on the erection of a three-story addition to the plant of the Kelly-Springfield Tire Company at Akron, O., which will cost about \$20,000.

ECONOMY OF FREIGHT HANDLING.

Possibilities Through Special Equipment for Limited Haulage Service.

Those who have haulage to do often disregard the possibilities to be obtained by special equipment for quick handling of vehicle freights, believing that the expense entailed does not justify the construction of what may assumedly be needed for a comparatively short time. The supposition is that unless a work is continuous or of considerable duration expense in connection with it is needless, and the saving that might obtain would not warrant equipping it so that labor and time may be minimized.

An example of the possibilities, however, and of the good judgment that was used, may be found in the case of J. F. Kulp & Sons, Buffalo, N. Y., a concern that owns four Pierce-Arrow five-ton trucks, and which had contract for hauling all the marble to be used in the construction of the new Catholic cathedral at Delaware avenue and Utica street, in that city. The building is to cost \$1,500,000 and the edifice will include 590 carloads of marble, about 450 of this to be for exterior and about 140 for interior work.

The stone could be easily defaced and for that reason could only be handled carefully, and when the haulage was begun much time was lost in loading at the cars and unloading at the site. Cranes were used at the cars and the unloading was by hand, each piece being handled separately. To economize, a number of "skips" or shallow boxes were built, these being mounted on small wheels so that they could be moved readily and quickly, and at the building site a platform was made with a runway to the ground. From the run plank ways were laid when necessary.

Some of these "skips" were left at the cars and these were loaded by the cranes when the trucks were

moving. The trucks carried the "skips" and the loads to the cathedral, where they were pushed on to the platform and they were left for the workers to handle at convenience, and empty "skips" were taken back to the cars. On arrival the empties were unloaded, loads quickly placed and return made without loss of time of the truck or of the men at either end. The breakage was reduced to practically nothing, and all delays were avoided. One truck in a nine-hour day hauled between 50 and 55 tons of marble, the round trip averaging about eight miles.

JERSEY ABANDONS NEW FEE BILL.

The bill that has been pending in the New Jersey legislature providing for the licensing of motor vehicles by classification of weight and horsepower, which was introduced at the instance of Governor Fielder, and which was expected to increase the revenue of the state approximately \$500,000, has been withdrawn, and there is little probability that a substitute will be presented. According to the bill the pleasure cars were divided into three classes by weight—not exceeding 2000 pounds, more than 2000 and not exceeding 3000 pounds, and more than 3000 pounds—and five classes by horsepower, where the weight was less or exceeded the above ratings with the standards of 22 horsepower, of more than 22 horsepower and less than 36, and for 36 horsepower or exceeding it, the fees being 50, 60, 70 and 80 cents and \$1 a horsepower. The bill provided that freight vehicles weighing more than 4000 pounds should pay \$2 additional.

MOTOR TRUCKS BUILDING EXPOSITION.

The work of constructing the grounds and buildings for the Panama-Pacific International Exposition, now progressing at San Francisco, Cal., and which has considerably advanced, has been thus far accom-

plished without the use of horses for haulage, and there is little probability that animals will be utilized for any purpose in connection with the development of the site or the structures upon it. There are numerous railroad sidings that reach the grounds, but the material must be moved from the cars, to say nothing of what is received at the piers in the city, and all of the haulage has been done with motor trucks. This is probably the first undertaking of such proportions, and certainly the first international exposition which was constructed without the use of animals for haulage.

Pierce-Arrow Five-Ton Truck Used with "Skips" for Hauling Marble for a New Cathedral at Buffalo, N. Y.

THE SIGNAL 1500-POUND DELIVERY WAGONS.

SPECIALIZING on a single type of vehicle that is believed will meet the requirements of the greatest number in need of highway transportation equipment, it being a unit of a size that is regarded as most practical and useful, the Signal Motor Truck Company, Detroit, Mich., has developed a 1500-pound delivery wagon chassis that, while conventional in every detail, is designed to afford maximum service at a minimum operating expense. Regarded from any point of view the Signal machine is not an untried construction. It is built of components that can be considered the best development of the industry, being produced by some of the largest and most responsible manufacturing concerns identified with vehicle building, and these products have been proven by continued service to be enduring and equal to every demand made of them.

Instead of following experimental development the company decided to build one size of machine from units that had been established as standards, and with this purpose its engineers selected those products that were recognized for their quality. One

reason for this was that besides

the attention the company can give, the owners of these machines have at their command the resources of the makers of the units, which insures to them service that is certain to continue and at comparatively small expense. This policy means the production of machines that, while sold for a moderate price, are constructed of high quality material, and, concentrating on a single type, the production cost is minimized—two important considerations for the purchasers.

The Signal wagons are assembled by a factory organization that is extremely efficient. Unusual care is taken that every machine produced will be up to a high standard. In the completed chassis are found Continental motors with Eisemann ignition systems, Hartford clutches, Covert transmission gearsets, Russell jackshafts, Detroit springs, Timken front and rear axles, Gemmer steering gears and Hyatt roller bear-

ings, which have been selected of proportions to have extremely high factors of safety, and the assemblies are well harmonized and have excellent appearance.

Emphasis may be made that nothing experimental has been accepted, and standard practise has been followed, but endeavor has been made to have a construction that is balanced throughout and that is accessible.

Features of the Motor.

The motor is a four-cylinder, water-cooled, vertical L head type, with the cylinders cast en bloc, with cylinder bore of 3.75 inches and stroke of 5.25 inches, mounted under a hood. The motor has a rating of 22.5 by the S. A. E. standard, but is claimed by the maker to develop more than 30 horsepower by brake test.

The construction is with ample factors of safety and all parts have liberal proportions. The block is cast with a large water jacket head that insures freedom of water circulation; the crankcase is an aluminum alloy, the lower half containing the oil reservoir and the upper section carrying the main bearings; the pistons have four rings and five oil grooves; the wristpins oscil-

late in bosses in the piston walls; the connecting rods are I beam construction; the camshaft is forged with the cam integral and carefully hardened and ground; the crankshaft has large bearings and the crankpins are ample, and flanges insure against end thrust; the timing gears are helical to eliminate noise; the bearings are nickel babbitt specially fitted, with steel shims for the connecting rods; the valve ports are large and the valves have full clearance, with nickel steel heads and carbon steel stems, electrically welded, and operated by tappets of the mushroom type; the valve mechanism is enclosed by two easily removable plates.

Lubrication and Cooling.

The motor is lubricated by a force-feed constant level system, the oil being drawn from the reservoir through a filter in the base by plunger pumps driven

Front View of the 1500-Pound Signal Wagon Chassis, Showing the Built-Up Radiator and the Generally Sturdy Construction.

Side View of the Signal 1500-Pound Wagon Chassis, Equipped with Open Express Body, This Being a Standard Equipment.

by eccentric on the camshaft. The lubricant is forced through a copper tube to flood the timing gears and the rear main bearings, and then drains to the crankcase, where it is distributed about the interior of the engine case by the sweep of the connecting rods. The oil reservoir can be drained and the filter cleaned conveniently. The engine is cooled by a circulation of water through the jackets and a large radiator of the built-up truck type, the centre section being fitted with finned vertical tubes, and the head and base and the side columns are castings from motor cylinder iron. The centre section is retained by a series of bolts and can be easily removed. This radiator is mounted on the dropped front cross member of the frame and is not affected by the weave of the frame. The water is circulated by a double-bearing type of centrifugal pump and radiation is assisted by a ball bearing fan mounted on an adjustable bracket, driven by a flat belt from an extension of the water pump shaft.

The ignition system consists of an Eisemann high-tension truck type magneto that is installed with a fixed spark, and the cable leads are protected by fibre conduits. The carburetor is an automatic float feed type that is claimed to supply a satisfactory mixture at all operating speeds. The fuel supply is controlled by a hand lever on the steering wheel and a foot accelerator. The motor is fitted with a centrifugal type governor which limits the speed of the vehicle on the highest speed ratio to 18 miles an hour. The fly-wheel is bolted to the rear flange of the crankshaft.

The clutch is a Hartford construction, being a cone of pressed steel 15.75 inches diameter with 2.625 inches face, with leather facing. The clutch has capacity to transmit 45 horsepower. Beneath the leather facing are six flat adjustable springs that insure easy engagement. Both the spring load and the declutching stress are taken by the highest grade of ball thrust bearings, these being

of the grooved type, with hardened and ground ball races. The declutching bearing is housed in a grease tight case, which does not revolve save when the clutch is disengaged, this minimizing the wear usually imposed upon bearings. The driving shaft is a Hartford product, 1.375 inches diameter, of alloy steel, with block and trunnion type joints, the trunnions, blocks and couplings being hardened and

ground and housed in grease tight cases.

The transmission gearset is a Covert design and construction, selective in its operation, having three forward speed ratios and reverse, the third or high ratio being direct through jaw clutches. The gears and shafts are of 3.5 nickel steel, the gears being carefully cut and the shafts ground and heat treated. The main and countershafts are mounted on Hyatt high duty roller bearings and the stub end of the main shaft is carried on a Standard roller bearing. The bevel pinion of the main shaft is backed by a grooved plate type ball thrust bearing. The gearset is assembled in combination with the jackshaft, and a torque arm is carried forward from the gearset case to the centre cross member of the frame, the forward end of the arm being spring supported.

Jackshaft and Axle Construction.

The jackshaft is a Russell production and is specially designed for heavy duty truck service, the gears and shafts being of heat treated nickel steel. The differential and the shafts are mounted in Hyatt high duty bearings, the thrust of the bevel or ring gear being taken by grooved plate type ball thrust bearings. The jackshaft floats in hangers rigidly fastened to the frame side members, and has a universal action in these hangers, rocking in unison with the movement of the torque arm of the transmission gearset casing. The jackshaft sprockets are of high carbon steel and are case hardened. They are easily removable when replacement is necessary.

The Signal 1500-Pound Wagon Chassis, with the Regular Equipment, Before the Installation of a Body.

The front and rear axles are Timken construction, heavy duty truck types, and are made of high carbon steel, heat treated. The front axle is two by 2.75 inches, and the rear axle 1.75 by 2.5 inches, the front being an I and the rear a rectangular section. The spindles of the front axle are 1.9375 inches diameter at the inner bearing and 1.375 inches diameter at the outer bearing, and the spindles of the rear axle are two inches diameter at the inner bearing and 1.625 inches diameter at the outer bearing. The axles are fitted with Timken roller bearings and hubs, the hubs having bolted on steel hub caps.

Frame and Spring Detail.

The frame is constructed from pressed special alloy steel channel section, .1875 inch thickness, 4.5625 inches width and varying in depth from 1.75 inches at the motor arms to 3.75 inches at the centre cross member, and to 2.5 inches at the rear end. The forward end of the frame is "necked" to decrease the turning radius. Both the centre and the rear frame cross members are 2.5 inches width and the full depth of the side members, being reinforced by unusually large gussets at both top and bottom.

The frame is suspended on springs made by the Detroit Steel Products Company, of special alloy steel and designed for truck service, which are fitted with a patented lubricating device. The front springs are 44 inches length and 2.25 inches width, and the rear springs are 50 inches length and 2.5 inches width. The spring eyes are bushed with phosphor bronze and grease cups are fitted. Hardened and ground bolts carry the suspension shackles, which are free to oscillate. The rear end of the frame is carried well down inside the springs, resting on heavy round cross bars that are extended through the lower ends of the spring shackles, this construction lowering the body and loading platform, as well as minimizing side sway. The minimized motion is an important factor where large bodies are used. The springs are secured to the axles by heavy clips bent over semi-circular spring saddles, this eliminating right angle stresses, the clips being held by double nuts.

The radius rods are heavy, open I section steel castings that have practically a universal action.

Forward End of the Signal Chassis, Without Dash or Footboards, Showing the Motor and the Control Pedals and Levers.

These rods are adjustable at the forward ends by a link threaded at either end that is retained by clamping bolts. The rear end is pivoted by a vertical pin to a brake carrier which is free to rotate on the rear axle, and the forward end is coupled to the jackshaft hanger by a spherical bearing and cap, so that there is no stress upon the rod, no matter what the movement of the springs or rear axle, aside from the driving thrust. The driving thrust of the radius rods is taken by the jackshaft hangers and the frame, and not by the jackshaft.

Wheel Equipment.

The wheels are made of selected second growth hickory, each having 12 spokes of 1.625 inches and 1.75 inches square section for the front and rear wheels respectively, with felloes designed to take the S. A. E. demountable rims. The wheels are equipped with solid band tires of the standard makes, standard demountable types, 34 by three inches forward and 36 by 3.125 inches rear. The drive from the jackshaft to the rear wheels is by chains of 1.25 inches pitch, .75 inch diameter of roll and .625 inch width between the side plates. The steering gear is a Gemmer design, this being a worm and full sector to minimize wear, operated by a 16-inch hand wheel. The gear is fitted with grooved plate type ball thrust bearings. The steering gear linkage is heavy and is carried behind the front axle to protect it against striking road obstructions.

Details of Control Members.

The machine is driven from the left side. The clutch pedal is at the left and the service brake at the right of the steering column. The fuel supply is by accelerator pedal. Applying the service brake automatically reduces the gas flow and the motor is reduced to

The Dash, Gasoline Tank, Footboards and the Operating Members of the Signal Chassis.

idling speed. The ignition requires no attention. The gear shifting and the emergency brake levers are located in the centre of the footboard at the right of the driver, with the shifting lever nearest, and the driver can enter his seat from either side without obstruction.

The brakes are of unusually large size and are of the internal expanding type, the service brake being on the jackshaft. The brake drums are 12 inches diameter and the shoes are 1.5 inches width, being faced with asbestos fabric. The brake drums are of steel. The braking effect is absorbed by the frame through the jackshaft hangers. The emergency brake shoes are mounted on the rotating carriers on the rear axle, are 2.5 inches width and 15 inches diameter, and expand within steel drums bolted to the wheels, which also carry the driving sprockets. These brake shoes are also faced with asbestos fabric. All brakes are cam actuated and are extremely effective.

With the governor set at 18 miles an hour the machine will make 12 miles on the second speed and 6.75 miles on low speed, the ratios being 7.5 to 1, 11.25 to 1 and 20 to 1, these indicating the difference in the propelling force on the low speed ratios. In designing the chassis care was taken to insure accessibility and convenience, and the gasoline tank is mounted back of the dash, with the filler cap at the right side, so that it may be filled from the step. The tank is well above the motor and there is a good flow of fuel to the carburetor on any grade the machine can climb. The shut off cock and the sediment trap are reached from in front of the dash. The arrangement of the tank insures warming the fuel

during cold weather, which is productive of greater operating economy. The standard equipment of the chassis is the driver's seat with spring cushion and upholstered back, front mudguards, running boards, dash and tail lamps and horn and tools.

The chassis as shipped has a priming coat of paint, but if ordered finished it will be painted to specifications. The wheelbase is 115 inches, with 56 inches tread forward and 60 inches tread rear, this design being to install a full sized body between the wheels. The truck can be turned without backing in a 34-foot street. With standard bodies the loading space back of the driver's seat is 96 inches length and 48 inches width, and the height of the platform is 32 inches above the ground. As the floor in front of the driver's seat is flat, when specially long space is desired an opening can be made so that loading can be done the full length between the dash and the tail gate, which is 138 inches.

TO PROTECT GARAGE OWNERS.

The Eastern Garage Keepers' Protective Association has been incorporated in New York City by Chester S. Walz of Glenbrook, Conn.; Thomas C. Walz of Pelham, N. Y., and John A. Samborn of New Rochelle, N. Y., which has been created by the same interests, and will be maintained with practically the same objects, as is now obtained with the Hotel Keepers' Protective Association. The association is to sell membership privileges, which will be good for a year, and during that period will supply its members with the names of all persons whose credit is known to be doubtful, this information being furnished by the members and distributed by the organization, which will serve as a clearing house. The cost of membership varies with the proportions of the business.

The H. J. Koehler S. G. Company, New York City, has appointed E. R. Marsters travelling representative for New England for the sale of the Koehler one-ton wagons. Mr. Marsters is well known in this section, having for five years been engaged in selling light weight machines in this territory.

ROAD BUILDERS' CONVENTION.

The annual convention of the American Road Builders' Association will take place at Chicago in December, this place of meeting being decided from the fact that its location is accessible from all parts of the United States. In connection with the convention will take place a road congress, in which all organizations interested in road development will be asked to take part, and it is probable there will be a very extensive exhibition of road building machinery. The details of the convention will be arranged by George W. Tillson, E. L. Powers and R. A. Meeker, they constituting the executive committee of the association. One of the endeavors of the association and its committees during the present year will be to interest every national association devoted to road building and improvement to unite in a national convention annually.

SCHOEPF TALKS TO ELECTRIC MEN.

T. H. Schoepf, an engineer associated with Westinghouse Electric & Manufacturing Company, East Pittsburg, Penn., spoke at the monthly meeting of the Electric Vehicle Association of America, held at the rooms of the association at 29 West 39th street, New York City, his subject being "The Performance Characteristics of Electric Motors and Their Influence on the Operation of Electric Trucks". The meeting was largely attended and the paper was listened to with much interest.

TRAFFIC REGULATION WORK.

The work of the citizens' street traffic committee of New York City, to be carried on in conjunction with the police control of street use of vehicles, and in co-operation with different civic bodies, has been actively begun and promises to have very practical results. Committees have been appointed to study and investigate different conditions, and one headed by George H. Duck, president of the Motor Truck Club, is to examine and report on the size, weight and load of vehicles that should be permitted to use the streets of the city. Prof. Arthur A. Blanchard of Columbia University is chairman of a committee that is to study the needs and make recommendation of whatever additional legislation, either state or municipal, that will better regulate street traffic, and James K. Orr is chairman of a committee that is considering the bet-

ter means of removing snow from the streets of the Metropolis.

DETROIT DOGS RIDE IN STYLE.

Detroit is regarded as the centre of motordom in that more machines are in use in proportion to population than any other city in the world. One reason that contributes to this result is the very large number of manufacturers of motor vehicles, accessories and equipment, and a good part of the residents not only are interested in the exploitation of motor cars, wagons and trucks, but the comparatively level country attracts through comparatively economical operating cost.

The Detroit municipal departments are practically all motor equipped, and this applies to some of the offices that would seemingly not have sufficient business to justify the purchase of special vehicles. For instance, the police department has just placed in service a new wagon equipped for the uses of the men who capture the stray dogs of the city, and this was designed with a view of economy as well as utility.

The machine is a Commerce 1000-pound delivery wagon chassis on which is installed an enclosed body that is partitioned with screens, making compartments in which a number of animals can be carried separately, whether or not vicious, without possibility of the creatures rioting and being disorderly, and from which they can be removed without probability of escape. The wagon is large enough to meet all requirements and it is much lighter than that formerly used, there being a considerable saving in operating expense. The machine has a cab in which the one man who drives it is well protected in cold weather and storms, and the body is sightly, despite the use made of the vehicle. The compartments are fitted with doors at the sides and end. The satisfaction obtaining with the first Commerce machine led to the purchase of the second machine of the same make.

Commerce 1000-Pound Delivery Wagon with the Special Body Designed for the Dog Catcher's Service of the Detroit, Mich., Police Department.

ADVERTISING RATES.

Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.

Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.

Entered as second class matter, February 25, 1911, at the Post-office at Pawtucket, R. I., under the Act of March 3rd, 1879.

BOSTON'S SUCCESSFUL TRUCK SHOW.

The Boston motor truck show, the national exhibition for 1914, was in every way a success. The number of exhibitors was large and representative of the industry and practically every type of vehicle was displayed. The noticeable absence of freaks or untried constructions demonstrated that for service machines the designers have practically united upon designs that have been proven by continued practise and that they have found the public unwilling to invest in what is in any way regarded as uncertain.

The simplification of the machines was noteworthy and if changes had been made these were of what might be considered minor details, although necessarily important from the viewpoint of endurance. There is no question that the industry has reached a basis of commercialism, and that the purpose of builders will be to develop a single standard and continue this either as one or several types. Body development, however, has hardly been begun, and now that this is considered engineering work there is every reason to believe that material progress will be made.

SELLING TRUCKS ABROAD.

The manufacturers of motor wagons and trucks who are considering exploitation of foreign markets, if they desire to be successful and to retain business that can only be developed at such expense that its value is evident, must make provision for supplying parts and

giving practically the same attention as other concerns competing with them. One can parallel the condition to be met in the experience of those selling foreign vehicles in America, but in addition to this is the need of the owners for continuous service, and insurance against unnecessary delay is a decidedly important factor.

One of the best known American pleasure cars was exploited in an extremely promising foreign market by an unusually able representative, and because the company making it, which was one of the largest of the American industry, did not carry stocks of parts and have the same protection for those using its machines that it provided in its home market, the concern not only sacrificed a large amount of money, but caused its production to be seriously discredited. It is needless to state that this result was caused by management so poor that one will wonder why it was tolerated.

Companies desirous of foreign business had best concentrate on one or more markets and develop these with even greater care than is given to American customers, because reputation of both vehicle and manufacturer are dependent on the satisfaction of users.

SELECTING TRAFFIC ROUTES.

The majority of those in charge of highway transportation services are content to let the drivers choose the routes through which their vehicles shall be driven, and this means that the men in charge of the actual haulage believe that it is well to have the employees follow whatever highways they please without regard to traffic conditions, congestion or the state of the paving, when full knowledge of the probable cause for delay would dictate specifying the streets or roads. Unless there is some incentive the average driver is not specially anxious to do all he can in a day, and this fact, combined with retardations that cannot be avoided, means loss of time. Familiarity with locality maps and knowledge of construction and temporary obstructions would be extremely valuable information for the average head of a shipping department.

EXPANDING BUSINESS WITH TRUCKS.

The estimated cost of operating a vehicle is assumedly a fair basis on which to judge its economy, but there are other factors that must be considered in connection with its use. None is of greater importance than the possibilities for business expansion. If limited by the use of animals, there may be the best of reasons why development can follow the utilization of motor equipment, especially when the machines can be worked for a much longer period daily. Fixed charges do not increase, no matter whether operated six or 24 hours a day, and that there is no loss in efficiency from practically continuous use, two elements of vital potency.

ELECTRIC VEHICLE PRACTISE.

Influence of Temperature upon Electrolyte and the Variations of Densities Shown by Hydrometer Tests with a Given Acid Volume---Methods of Correcting Readings to Standards and Testing by Cadmium to Determine Capacity.

By William W. Scott.

THE critical point of lead-acid secondary cells in operation may be said to be 100 degrees Fahrenheit, and any temperature in excess of this is decidedly dangerous. That is, deterioration will probably result and a practical insurance is to operate the battery at such a maximum that the critical point will not be reached. The conditions that are recognized as engineering standards are eight hours' charge and discharge, with the temperature maintained at 70 degrees throughout the period. Authorities on storage battery construction maintain that the maximum temperature should not exceed 90 degrees, and strongly advise against operating at a temperature of 100.

When the temperatures are high the porosity of the plates is increased, the chemical activity is greater, and the tendency to sulphation is more pronounced. The pasted forms of plates are less susceptible to damage from heating than are those of the Plante type.

Manufacturers of secondary cells are practically agreed as to limitations of temperature, although there is some variance as to the maximum permissible. While no one type of cells has been considered, and statements can be applied generally, it is believed well to establish the specific directions of some of the best known makers with reference to cells that are recognized as standard and are in common use.

Exide and Exide-Hycap cells: "A direct indication of excessive overcharge is a very noticeable increase in the temperature of the cells. The temperature of a battery must not be allowed to exceed 110 degrees Fahrenheit, the cells in the middle of the battery being used as a guide. If the temperature is found to be running up toward the safe limit (110 degrees F.), the charging rate should be reduced or the charge stopped for a while".

Philadelphia cells: "The temperature must not exceed 100 degrees F. If the temperature nears this point, the charging current should be reduced, or the charge stopped until the temperature has fallen.

* * * Do not let the temperature of the battery rise above 100 degrees Fahrenheit at any time".

LBA cells: "The temperature of a battery must not be allowed to exceed 100 degrees Fahrenheit, the cells near the middle of the battery being used as a guide. If the temperature is found to be running up toward the safe limit (100 degrees Fahrenheit), the charge should be reduced or stopped for a while".

Gould cells: "The best results will be obtained at a temperature between 70 and 90 degrees Fahrenheit (21.1 to 32.2 Centigrade). A high temperature will tend to disintegrate the active material, attack the plate grid, char the wood separators and warp the rubber jars. As the temperature exceeds 90 degrees Fahrenheit, the more pronounced these actions will

Fig. 1—Dotted Line Represents Cell Voltage, the Upper Curve the Cadmium Reading Against a Positive Plate and the Lower Curve the Cadmium Reading Against a Negative Plate.

become. The extreme temperature limit should not exceed 105 degrees Fahrenheit under any circumstances. The importance of interrupting a charge and allowing the battery to cool can be readily appreciated. The effect of a low temperature is to reduce the available capacity of the battery. This seeming lack of capacity is only temporary, as the capacity will be regained when the temperature is brought up. In keeping track of the temperature during charge, the inside cells instead of the outside cells should be read, as the former will be a few degrees higher than the latter".

US cells: "If, while charging, the battery commences to heat, which sometimes occurs if the temperature of the room is high, stop the charge and allow

the battery to stand until it cools. The temperature of the battery should never exceed 100 degrees Fahrenheit while the battery is charging".

One will note that these statements apply to charging temperatures, specifying the extremes that may be permitted. There is no good reason why these maximums should be reached, as nothing practical can be gained by allowing them, and there is probability of damage that can only be avoided by observing requirements of manufacturers for operating, as follows:

Exide and Exide-Hycap cells: "Experience has shown that the best results, both while charging and discharging, can be obtained when the battery temperature is between 70 degrees and 90 degrees Fahrenheit. A considerably lower temperature will materially reduce the available capacity; this reduction, however, should not give rise to the feeling that the battery is failing, as a return to normal temperature restores the capacity of the battery; on the contrary, however, if the temperature for any considerable time is above normal, the wear on the plates is excessive".

Philadelphia cells: "The battery should be kept

difference in these cells. This does not mean a wide difference in principle, but such variance that to obtain maximum results the instructions relative to each make of cell should be followed literally.

The variation is principally in the standards fixed for the electrolyte, and that these may be thoroughly understood the following are given for the makes of cells specified:

Exide and Hycap-Exide cells: "With the battery fully charged, the specific gravity of the electrolyte should be between 1.270 and 1.280, but due to sloppage and loss by spraying, however, there is a gradual lowering of the gravity, so for this reason it may be allowed to fall to 1.250 when fully charged; then gradually restore to normal by the addition of 1.275 specific gravity electrolyte when replacing evaporation".

Philadelphia cells: "The electrolyte of a fully charged Philadelphia battery should be 1.300 specific gravity at 70 degrees Fahrenheit".

LBA cells: "With the battery fully charged, the specific gravity of the electrolyte should be between 1.275 and 1.300".

Gould cells: "It is therefore advisable to keep the density fairly close to 1.275 specific gravity when the battery is fully charged. * * * The specific gravity of 1.275 herein given is figured at 80 degrees temperature".

US cells: "This must be a chemically pure, dilute sulphuric acid of 1.285 degrees specific gravity, or 32 degrees Baume, or a mixture of approximately one part pure acid to 2.75 parts distilled water by bulk or volume. * * * At the end of the charge the gravity should read 1.280 degrees".

Fig. 2—Dotted Line Represents Cell Voltage, the Upper Curve the Cadmium Reading Against a Positive Plate and the Lower Curve the Cadmium Reading Against a Negative Plate, the Cadmium Being Negative to Both Plates.

and charged in a moderately warm place during the winter. If it becomes thoroughly chilled, it will require a higher voltage to charge, and the mileage will be somewhat reduced".

LBA cells: "Experience has shown that the best results, both while charging and discharging, can be obtained when the battery temperature is between 70 degrees and 90 degrees Fahrenheit. A considerably lower temperature will materially reduce the available capacity; this reduction, however, should not give rise to the feeling that the battery is failing, as a return to normal temperature restores the capacity of the battery. On the contrary, however, if the temperature for any considerable time is above normal, the wear on the plates is excessive".

Gould cells: This was dealt with in the first statement.

The efficiency of every cell depends upon the electrolyte, and comparison of the practise specified by each maker will demonstrate that there is a material

From the foregoing one will understand there is sufficient variance with reference to temperature and density to justify the statement that each make of cell must have specific treatment. No purpose will be served by varying from the instructions specified by the manufacturers, for these have been established by careful experiment and experience, and were determined with accurate knowledge of possibilities. Based on practical results, nothing is lost by observing them.

The acid used in mixing electrolyte is assumed to be commercially pure, which is rated at 1.835 specific gravity. Taking this as a basis it is found that at 60 degrees an electrolyte having a density of 1.250 specific gravity will contain 35.50 per cent. of sulphuric acid, and that at 70 degrees it will show 1.247 specific gravity, at 80 degrees 1.244 specific gravity, at 90 degrees 1.241 specific gravity, and at 100 1.238 specific gravity.

Taking the Exide or the Exide-Hycap cell as an example, the maker specifies that the best operating

result is obtained at temperatures between 70 and 90 degrees, and assuming the average of the two, or 80, as that which will be satisfactory, and desiring an electrolyte of 1.275 specific gravity, it is found that this will contain approximately 39.75 per cent. acid. The exact specific gravity of a 39.75 per cent. acid solution is 1.277, which at 90 degrees would drop to 1.274, and at 100 degrees to 1.271. A solution that would have a specific gravity of 1.250 at 80 degrees would contain approximately 36.25 per cent. of acid, which shows that there is permissible a variation of 3.50 per cent. of acid before the cell will be so much reduced that restoration of acid is imperative. That is, when in a condition to do its maximum work a cell may range from 1.271 to 1.292 in specific gravity, according to variation of temperature without change of electrolyte density, and as the acid is gradually lost the density may lessen to a range of from 1.244 to 1.265, these limits representing the differences between 100 and 30 degrees.

One will observe that there is a difference of 21 degrees approximately in the reading of the specific gravity of an electrolyte containing a given volume of sulphuric acid because of temperature alone, between 30 and 100 degrees Fahrenheit, the density increasing as the temperature decreases, and this law or rule can be absolutely depended on. With this as a basis, and taking the range of specific gravities between 1.151, which represents the minimum density that will probably be reached in practise, and 1.306, which can be regarded as the maximum, there is a total of 155 degrees of the hydrometer scale. There is no reason why this variation of temperature and density should be worked out to degrees, for battery practise does not require this exactness, but it is entirely practical to tabulate this to a point where it will serve as a reference and be sufficiently close so that conditions can be determined very accurately.

The following tabulation has been prepared with an electrolyte composed of 1.835 acid as a basis, and a series of 16 different densities, from 22 to 42.62 acid has been stated. From each of these readings the densities with variations of 10 degrees of temperature, from 30 to 110 have been approximated, so that corrections can be quickly and readily made. Thus, if one desires to determine the condition of an electrolyte with reference to acid volume, this can be ascertained by taking the temperature and hydrometer readings, and comparing these with the tabulation. It will be seen that each per cent. of acid volume represents about nine points decrease or increase of the hydrometer reading, and that approximately each degree of temperature represents about .3 degree variation of the hydrometer reading. It will be noted by referring to the tabulation that a drop of 40 degrees in temperature is approximately equal to an increase of 1.38 per cent. (actual) acid. That is, a hydrometer reading of 1.277 at 80 degrees temperature will show an acid density of 39.75, and at 40 degrees will show an acid density of 38.37 variable with temperature.

The tabulation of acid volume and specific gravities and temperatures is as follows:

Per Cent. of 1.835	Degrees of Temperature, Fahrenheit									
	30	40	50	60	70	80	90	100	110	
42.62	1.315	1.312	1.309	1.306	1.303	1.300	1.297	1.294	1.291	
41.25	1.304	1.301	1.298	1.295	1.292	1.289	1.286	1.283	1.280	
39.75	1.292	1.289	1.286	1.283	1.280	1.277	1.274	1.271	1.268	
38.37	1.281	1.277	1.275	1.272	1.269	1.266	1.263	1.260	1.257	
37.00	1.270	1.267	1.264	1.261	1.258	1.255	1.252	1.249	1.246	
35.50	1.259	1.256	1.253	1.250	1.247	1.244	1.241	1.238	1.235	
34.00	1.248	1.245	1.242	1.239	1.236	1.233	1.230	1.227	1.224	
32.75	1.238	1.235	1.232	1.229	1.226	1.223	1.220	1.217	1.214	
31.25	1.227	1.224	1.221	1.218	1.215	1.212	1.209	1.206	1.203	
30.00	1.217	1.214	1.211	1.208	1.205	1.202	1.199	1.196	1.193	
28.50	1.207	1.204	1.201	1.198	1.195	1.192	1.189	1.186	1.183	
27.25	1.197	1.194	1.191	1.188	1.185	1.182	1.179	1.176	1.173	
26.00	1.188	1.185	1.182	1.179	1.176	1.173	1.170	1.167	1.164	
24.50	1.178	1.175	1.172	1.169	1.166	1.163	1.160	1.157	1.154	
23.25	1.169	1.166	1.163	1.160	1.157	1.154	1.151	1.148	1.145	
22.00	1.160	1.157	1.154	1.151	1.148	1.145	1.142	1.139	1.136	

The density of a secondary cell should never be permitted to fall below 1.150 specific gravity, and generally the minimum is 1.160 to 1.180, these two figures corresponding to 1.7 volts and 1.8 volts, so that when 1.7 volts is indicated at 80 degrees, for instance, the density of the electrolyte is about 24 per cent.

In charging, the voltage of a cell rises comparatively slowly for a period, then remains comparatively constant until considerable gas is liberated, and then rises until it again remains constant, at which time the maximum voltage may be regarded as having been reached. The voltage rise of a cell is best expressed by a curve, but it may be followed very logically by readings covering stated periods of the charging. As has been stated, the slow rise of the voltage at the beginning of the charge is due to the slower diffusion, and at the latter part of the charge the increased resistance, during which time the amperage is decreased, is an important factor. One can accept with certainty the fact that there is a uniform increase of voltage variation between pure sponge lead and lead peroxide electrodes between specific gravities of 1.050 and 1.300, and for this reason the density of the electrolyte and the condition as to gassing will give a positive and definite knowledge of the condition with relation to the charge.

A characteristic of every lead-acid cell is that it will, following either charge or discharge to what may be considered the highest or lowest voltage value, regain its normal voltage within a comparatively short time, and after the charging one may note the liberation of hydrogen gas from the negative plates. When this omission of gas, which is a loss of energy and will continue a short time, has ceased, the voltage of the cell will be found to be approximately its full open circuit value.

But the fullest efficiency cannot be realized from a cell unless action of the current and the electrolyte upon the plates is such as will establish full capacity. By this is meant that if one series of plates of the element is not fully charged the work that can be obtained will be represented by the difference between

the plate or plates least charged and those completely charged. This explains why a cell may be affected by a condition that may only be found with a single plate, and why such a cell will materially influence an entire battery of cells. For this reason the condition of each cell and each set of plates is important. Charging with the voltage and amperage indicated by instruments will develop need of investigation when the batteryman is experienced, but test only can determine the exact cause, and for this reason the gravity reading of the cells is regarded as being the more certain.

It is, however, practical to test the plates, and this is usually done with a cadmium tester, which can only be used with a voltmeter having a high resistance, for a considerable current flow will be developed and polarization will obtain. The best form of cadmium tester can be made by procuring two pieces of cadmium rod 2.5 inches length and .28125 inch diameter, and two pieces of hardened copper rod or wire 3.25 inches length and .15625 inch diameter. Holes should be drilled into one end of the cadmium rods a depth of .75 inch and tapped, and one end of the copper rods threaded and screwed into the cadmium, making solid contact. The ends of the copper and cadmium rods

sary, with certainty. If but one combination rod is used the voltmeter connection will need to be reversed to make the negative plate readings when the cell is being charged.

The voltage "across" a cell is obtained by contacting the positive and negative leads from a voltmeter firmly with the positive and negative terminals. With the form of copper-cadmium tester described, with the centres of the combination rods insulated with tape, the readings can be made by contacting the copper points with the terminals for the "across" readings, the sharpened points insuring good contact. When the cadmium readings are to be made the cadmium points should be kept wet with electrolyte or dilute sulphuric acid of approximately the same density, and can be moved from cell to cell in a glass or china cup.

Assuming that a cell has been discharged: With the voltage reading 1.8, which is a reasonable minimum, the cadmium test can be made. With the cadmium covered with perforated rubber tube the end may be placed in the electrolyte without fear of it contacting with any of the plates. With the cell voltage stated the cadmium will be negative to both the positive and the negative plates, but the readings will show a voltage of approximately 2.05 volts between the cadmium and the positive plates, and between the cadmium and the negative plates .25 volt. The test should be made when the cell is discharging at normal rate, and the indication is obtained by subtracting cadmium-negative reading from the cadmium-

A Composite Tester of Copper and Cadmium Rod, Two of These Being Connected with a Voltmeter and Used to Test Cells for Low Capacity.

should be ground or filed to points, tapering for perhaps 1.5 inches from either end. The tester rods will, when finished, be five inches length. Through the centre of the end of the cadmium rods into which the copper rods are screwed, holes should be drilled of sufficient diameter to admit the end of wires extending to the voltmeter. These wires can be fixed permanently by soldering if desired, and the wire leads covered with a rubber tube. The cadmium ends of the tester should be covered with pieces of thin rubber tube perforated with small holes, after taping the centre for about two inches, at either side of the wires. Care should be taken to insure the cadmium being pure, otherwise it will contaminate the cell. After the tester has been made the cadmium portions should be placed in a small quantity of electrolyte for a short time, when they will become coated with cadmium sulphate, which should not be removed. The cadmium test is not usually needed unless in the case of cells that have been in use a considerable time and the elements somewhat deteriorated, or for the testing of low capacity cells. With the form of tester that has been described the voltmeter can be used for all purposes and the cadmium test can be made, whenever neces-

sary, with certainty. If but one combination rod is used the voltmeter connection will need to be reversed to make the negative plate readings when the cell is being charged.

When the charging has been begun the cadmium is negative to the negative or sponge lead plates, but as the charging advances the difference between the two lessens and eventually the cadmium becomes positive to the negative plates and negative to the positive plates, due to the reduction of the sulphation and the transformation of the lead sulphate to lead peroxide. When the charging is complete the reading between the cadmium and the positive plates will show about 2.30 volts, and between the cadmium and the negative plates .20 volt, but as the reading is in opposite directions the voltages are added, this giving a total of 2.50 volts. The illustrations are for the purpose of familiarizing the reader with the manner of reading the indications of the cadmium tests.

In some instances the reduction of the lead sulphate on the plates is not equal in charging, and until this reduction is accomplished the test will show the negative plates are positive to the cadmium. Instances have been observed where the negative plates re-

mained positive to the cadmium up to as high as 2.50 volts, the positive plates being completely charged. Such cells always show low capacity, but when the sulphation is removed by continuation of the charging, which will be evidenced by the cadmium tests, efficiency is restored. One can safely regard a cell as charged when the negative plate will show a reading of from .05 to .10 volt against a cadmium tester, the cadmium being positive, and when a negative plate shows a reading of .25 volt against a cadmium tester, the cadmium being negative and the plate positive, the cell may be regarded as discharged.

The following may be regarded as a summary of the cadmium tests for both charging and discharging:

Charging.	Discharging.
Beginning, Cell Voltage...1.80	Beginning, Cell Voltage...2.50
Cadmium is	Cadmium is
Negative to Negative Plate .25	Positive to Negative Plate .10
Negative to Positive Plate 2.05	Negative to Positive Plate 2.40
Voltage is difference in readings.	Voltage is sum of both readings.
Readings in one direction.	Readings in both directions.
Ending, Cell Voltage.....2.50	Ending, Cell Voltage.....1.80
Cadmium is	Cadmium is
Negative to Positive Plate 2.40	Negative to Positive Plate 2.05
Positive to Negative Plate .10	Negative to Negative Plate .25
Voltage is sum of both readings.	Voltage is difference in readings.
Readings in both directions.	Readings in one direction.

The charging and discharging readings should be made with the current flowing, at the beginning and end of the charging, start and finish of discharging, and during the charging and discharging at different intervals, care being taken that the cadmium does not contact with the electrodes, the points of the testers being firmly pressed against the terminals. It is not improbable that there will be a slight difference between the observed voltage of the cell and the voltage as determined by the cadmium tests, but this will be due to deflection between the cadmium and the negative plates.

In the use of the cadmium tester when the cell is charging the reading to positive is made by placing one copper point on the positive terminal and placing the cadmium point of the other terminal of the voltmeter in the electrolyte. When the cell is discharging, for testing, to illustrate, the negative reading to cadmium can be made by placing one cadmium point in the electrolyte and moving the copper point of the other terminal on the negative terminal. When the charge has been concluded the cadmium must be removed from the solution and contacted with the negative terminal, and the copper point removed from the positive terminal and the cadmium point placed in the electrolyte.

In the event of the charging voltage reaching 2.5 and the voltage not indicating between the negative plates and the cadmium, the cell is not fully charged, and the current should be continued to bring it to its actual capacity. Where the grids of the positive plates are a lead-antimony alloy the difference in the potential between the negative plates and the cadmium will probably be about .05 volt, at the conclu-

sion of the charge, but should the plates be of pure lead, with the cadmium positive to the negative plates the voltage may reach .12 or even .15 volt.

It is practical to make the cadmium tester with but one of the combination contacts, this being connected with the negative pole of the voltmeter, but the voltmeter connections will have to be reversed to take the negative plate readings when the cells are charging. It is understood that the cadmium tests are necessary only when cells are low in capacity and data are to be used for the purpose of restoring them.

At Fig. 1 are shown curves in which the dotted line represents the cell voltage during charging. The curve designated as + cad. indicates the potential of the positive plate against a cadmium tester during the charge, and the curve marked — cad. indicates the potential of the negative plate against a cadmium tester. At Fig. 2 are shown curves in which the dotted line represents the cell voltage during discharge. The curve designated as + cad. indicates the potential of the positive plate against the cadmium tester, and that designed as — cad. indicates the potential of the negative plate against the cadmium tester, in both tests the cadmium being negative to both the positive and negative plates.

By comparing the curves of Figs. 1 and 2 one will note that when the charge has progressed for about six hours the potential of the negative plate falls and when it has reached zero it becomes negative to the cadmium, a condition that is continued until the end of the charging. These curves were made with an average charging current of 37.5 and a discharge of 35.

(To Be Continued.)

WILL VOTE ON BOND ISSUE.

A proposition to authorize an issue of first mortgage bonds, to the value of \$1,500,000, payable in 15 years, has been made the stockholders of the United States Light & Heating Company, and the proposal will be acted upon at a meeting at Portland, Me., April 9. If the issue is authorized, the proceeds of the sale of the bonds will be available as working capital.

The plans of the company for expansion have been practically determined, and these comprehend increased production of storage batteries and engine starting and lighting equipment for gasoline motor vehicles. After May 1 the general offices of the company will be located at the factory at Niagara Falls, the purpose being to remove them from New York, leaving a sales and service station in that city.

The charter of the Keller Cyclecar Corporation, which was recently incorporated at Wilmington, Del., under the law of the state, authorizes capital of \$250,000 and the manufacture of motor trucks in addition to the production of highway vehicles and aircraft generally. The incorporators are H. E. Latter, W. J. Maloney and O. J. Reichard, all of Wilmington.

ELECTRICS FOR MAIL HAULAGE.

Postal Transfer Service Buys 20 G. V. Two-Ton Wagons for New York.

The Postal Transfer Service, Inc., a company that has contract for haulage of some of the mail on Manhattan Island, New York City, has purchased 20 two-ton General Vehicle wagons, which will be utilized in the general work of the concern. The contract has been made and the machines will be delivered as rapidly as they can be completed. This company succeeded to the business of the New York Mail Company, which had contract for the work for a considerable period, and the demands have been very much increased by the inauguration of the parcel post division of the postal service. The company was organized in the spring of last year and the bid made for what is officially known as route 407.012, was accepted in September.

The company has contract to haul all the mail between the general postoffice and the branches and the railroad terminals south of 42nd street, it being divided into three classifications. The "mail-messenger" class entails the haulage of the incoming European mail between the receiving pier and the general postoffice and the receiving pier and the outgoing railroad terminals, handling all of the mail brought into the city of this class; the "transfer" class is the haulage between the railroad terminals, this requiring trips to Jersey City, and the "station" class is the haulage between the general postoffice and the branch stations. This does not include the collection of mail at the substations or at the plants of individual concerns.

The firm began business with 80 two-ton and 20 one-ton gasoline machines, this including some of the equipment of the company that it succeeded, and the 20 wagons just bought will replace a similar number that has been in service until no longer dependable. The company expects that it will be necessary to increase its equipment to 1250 vehicles to take care of the business. The electric vehicles were purchased after inquiry into the service of the Motor Delivery Company, which has the contract for haulage of the mail north of 42nd street on Manhattan, to 180th street on the west side and to Fordham on the east side of the city, and since 1909 has used from 22 to 28. In 1913 the company's machines were driven a total of 336,000 miles in 304 days. The haulage is to and from branch postoffices and the 42nd street terminal. The company originally took over a horse vehicle contract and utilized electric machines, and has continued its service with them, using no less than 14 of these for parcel post work.

The Postal Transfer Service has established a garage at First avenue and 42nd street, where the electrics will be stored when not in use. The president of the company is H. Rowley and J. J. Cassidy is the vice president and in charge of the operating.

PRACTICAL OPERATING HINTS.

The automobile bureau of the New York Edison Company, New York City, has distributed to users of electric vehicles in the Metropolis and vicinity a card that is intended for the use of the drivers, this having on one side some very practical "Dont's for Winter", and on the reverse a list of the 24 emergency charging stations of the company, the addresses and the capacity in amperes for charging. These stations are generally in Manhattan, but five of them are in the Bronx. The capacities are 60, 100 and 200 amperes. The card is a convenient reference for the drivers in the event of emergency, and a copy can always be carried in a machine.

The tentative plans for the second European visitation of the Society of Automobile Engineers are for the party to leave New York City, Oct. 10, with the purpose of seeing the Paris Salon and the Olympia show in London, going first to Paris, thence to Turin and Milan in Italy, then to Lucerne in Switzerland, Stuttgart, Cologne and Essen in Germany, Brussels and Antwerp in Belgium, then to London. The itinerary is made up for 39 days' absence.

The Buchanan Electric Steel Company, Buchanan, Mich., has begun the production of cast steel wheels for service wagons and trucks which are of the disc type and built with hollow rim and cored hubs to insure lightness. The metal used is an alloy steel, heat treated to insure strength. Brake drums are cast integral with the wheels when desired. The wheels are built to conform to the S. A. E. requirements.

The Goodyear Tire & Rubber Company of Canada, Ltd., has elected these officers for the following year: President, F. A. Sieberling; vice president and sales manager, R. P. D. Graham; treasurer and general manager, C. H. Carlisle; secretary and assistant treasurer, C. J. Oille; superintendent, E. H. Koken.

The New England branch of the Vulcan-Bessemer Company, Boston, Mass., is now in charge of Charles E. Collard, who was recently manager of the truck tire department of the New York branch of the Goodyear Tire & Rubber Company, and who is well known in the industry and trade.

The Chicago branch of the Universal Motor Truck Company, Detroit, Mich., has been purchased by William A. Schaefer and F. H. Luther, who are continuing the business as the Chicago Universal Motor Truck Company.

The Pacific Tire & Supply Company has been incorporated at Seattle, Wash., with capital of \$700,000 by B. L. Gates, Austin E. Griffiths and A. K. Allen, to manufacture automobile tires and rubber specialties.

LOADING BY OVERHEAD CONVEYOR SYSTEM.

ECONOMY is a relative term. Business men who have given careful consideration to the subject of motor transportation are readily convinced that

still further reduced, requiring the services of a lesser number of men for a given amount of work, and eliminating the danger of making mistakes, since it is possible to make up orders and check them ahead of time without confusion and hurry at the last moment.

Telpher Loading Hand Trucks on Specially Designed Commercial Car Chassis in Service of M. A. Newmark & Co., Los Angeles, Cal.

economy and efficiency are very closely related. In other words, there are certain lines, at least, in which it is possible to effect a saving over horse drawn equipment only when the motor truck can be utilized to its fullest capacity, particularly with reference to time. This applies to practically all lines, when it becomes a matter of the greatest economy.

Within the past few years wholesale grocers have given unusual attention to the question of highway haulage. In many instances their travelling salesmen have been supplied with automobiles, the better to cover their territory and reach customers without depending upon railroad schedules. Possibly it was the success which attended this innovation which caused the heads of such firms to investigate the possibilities of motor trucks.

The advantages of motor equipment in this field are many, including the ability to make quick deliveries at the door of the customer, and the elimination of freight charges and the necessary additional handling of the packages. However, it is extremely essential that the truck shall be kept busy, and to this end many interesting plans have been devised. One of these is indicated by the accompanying illustrations.

The system is that employed by M. A. Newmark & Co., Los Angeles, Cal., and by its use it is stated that the company saves at least 45 minutes in loading each vehicle. In addition, the handling of packages is

position wherever wanted.

In practise the small trucks are loaded while the motor trucks are on a delivery trip, and as fast as the orders are received, by mail or over wire. When the motor trucks return the telpher picks up the empties and replaces them with filled receptacles in waiting, and there is almost no delay.

As will be noted by the accompanying illustrations, the telpher equipment includes an electric motor, with provision at the rear for the operator, who occupies a convenient seat and directs the placing of the hand trucks. Suitable belts, running over pulleys, are arranged to pick up the trucks and hold them suspended while the electric motor conveys them about the ware-

Indicating the Overhead System Employed to Place Hand Trucks in Various Parts of Newmark Wholesale House.

house. Several of these telphers are employed to accommodate the needs of the company.

The Newmark house is not only one of the first concerns on the Pacific Coast to use motor trucks in its business, but it is one of the largest users of such vehicles in Los Angeles. As soon as it had been demonstrated to the satisfaction of its officials that mechanical transports offered a means for increasing the range of action, practically all of its horse drawn wagons were replaced by automobile equipment.

For more than a year now it has been operating a fleet of 11 GMC trucks of 3.5 and five tons capacity. The overhead conveyor system described above was installed soon after the decision to utilize such vehicles was made, and this plan has played a very important part in the success of the enterprise. According to the officials of the company it has increased the efficiency of the trucks at least 30 per cent.

GROW SELLS REPUBLIC TRUCKS.

The George Grow Automobile Company, 321-3 Columbus avenue, Boston, has been made the New England agent for the distribution of Republic one-ton wagons, made by the Alma Motor Truck Company, Alma, Mich., which were exhibited at the Boston motor truck show. This company is the largest firm of the kind in New England and is widely known.

The Republic machines are assembled from components made by some of the leading manufacturers in the industry, who specialize production and standardize after exhaustive tests to determine engineering and quality of material used. The chassis include Continental motors, Eisemann magnetos, Hartford cone clutches, Covert transmission gearsets, Russell jackshafts, Lewis springs, La Vigne steering gears and other equally well known materials in frames, bearings, etc., and they are built with left side drive and centre control levers.

The announcement is made that agencies will be established in different parts of New England and that those who desire can purchase these machines on time payments.

C. W. Richards, for several years factory manager for the Stevens-Duryea Company, Chicopee Falls, Mass., has been engaged as superintendent of production by the Driggs-Seabury Ordnance Corporation, Sharon, Penn., which is systematically strengthening its organization to insure the increased volume and perfected product necessary through several large contracts which were entered into at the opening of the year.

John E. Dray, formerly connected with the Interstate Sales Company, San Francisco, Cal., has become associated with the Galveston, Tex., Motor Car Company, and will specialize his endeavors in the sale of GMC trucks in the different towns and cities along the Texas coast.

BREWERY FULLY MOTORIZED.

The Los Angeles Brewing Company, Los Angeles, Cal., on Jan. 31 by auction sale disposed of all its horse equipment, removing from service 52 animals, 12 wagons and three buggies, and 13 sets of harness. The company announced this disposal to the highest bidders, because of it having purchased White motor wagons and trucks for the use of its shipping and distributing departments.

The company acquired its first motor truck three years ago and worked it in all kinds of service with such success that others were bought. The efficiency of the machines was so satisfactorily proven in comparative work with horses that nine vehicles, ranging from 3000-pound wagons to five-ton trucks, were ordered. When these were delivered the company advertised its horse equipment for sale, it having then motors for all purposes. The small machines are used for house-to-house deliveries, and the trucks are utilized for keg and barrel haulage.

WHITE TAXICAB SERVICE.

The Taxicab Association, Ltd., has inaugurated business in New York City with an equipment of 26 White cabs, this being one of the largest concerns to engage in public service in New York since the abolition of the exclusive privileges controlled by leading hotels, and the regulation of the cab stands by the police department. The president and general manager of the company is M. Bundy Cole, who was manager of the National Bank of Nicaragua for a number of years, and who was responsible for the change of the monetary system of Nicaragua from paper to gold. C. A. Jones, president of the Nicaragua Railway Company, is vice president. The statement is made that other companies are now organizing, and that one will engage in business as soon as the equipment and headquarters can be obtained, on a considerably larger scale.

BROWN COMPANY NOT INSOLVENT.

The Brown Commercial Car Company, Peru, Ind., which was petitioned into insolvency recently, has filed a plea that it is not insolvent and that the facts in the petition are not a true representation of conditions. The plea has been referred to a referee and upon this decision will be based further proceedings.

The Motor & Accessory Manufacturers will move to new headquarters in the Aeolian building, 29 West 42nd street, New York City, about April 1, from No. 17 in the same thoroughfare.

The International Motor Company has established its executive offices at its service station at West 64th street and West End avenue, New York City, removing them from Broadway and 57th street.

HIGH CLASS SCHOOLS WITH MOTOR 'BUSES.

THE necessity of good education is unquestioned by all, and one of the most cogent arguments made by those who advocate city life is the greater opportunities educationally than are practical, or even possible, in the country. The rural community can afford elementary schools, but the limited number of scholars and the necessarily larger expense of more advanced education, as well as the distances that are almost if not quite prohibitive for boys and girls to travel without conveyances, are conditions that are generally met with by those who are desirous of promoting as liberal education as is possible in country life.

The condition stated has frequently been met to a certain extent by several towns or districts uniting to secure better supervision of schools, this insuring the service of well qualified superintendents, but distance has been the condition that has always limited possibilities, because of the lack of transportation. Where street or steam railroads are available the solution is simple, but obviously these serve but a small part of the population. There is another aspect—the cost of transportation—for where this must be met by the parents in addition to the expense of supporting the children any material item may be a burden, if not a prohibition.

The more recently settled sections of the country must meet these educational problems more generally than those portions more thickly populated, but examples of the possibilities for promoting education through the use of motor omnibuses may be taken from California, these being the unity of several towns for establishment and maintenance of high schools, and providing transportation for the pupils.

From a practical point of view one large school with efficient teachers and comprehensive courses is far superior to several schools and inferior organizations that might be possible within walking distance, and there is also a decided benefit in consolidation where the matter of transportation can be satisfactorily dealt with.

At distances varying from nine to 15 miles apart, in the vicinity of Fullerton, a prosperous town in Orange county, California, lie five school districts—Olinda, Placentia, La Habra, Randolph and Orange-thorpe. Each of these districts has supported grammar schools for many years, but the problem of giving their graduates the benefit of a high school education was a very serious one. The motor truck has solved this difficulty.

About two years ago the five outlying districts combined with Fullerton in the formation of a union high school district, and three 1.5-ton trucks, with passenger bodies, were purchased in order to transport the pupils thereto. The system worked out so satisfactorily that the high school recently added two fine new 'buses to the passenger service. More than 100 pupils, or approximately half of the enrollment, are now being conveyed between their homes and the school in these vehicles.

The motor 'bus equipment represents a total investment of \$13,700. The chauffeurs are high school boys, who take turns at the wheel, and receive 50 cents a day for their services. There is a large garage on the school grounds, and a mechanic is employed constantly to care for the trucks and keep them in good condition. Special care has been taken to provide for the comfort of the scholars, some of whom travel no less than 26 miles a day in the 'buses.

As a result of the concentration noted, the Fullerton union high school district has been able to erect a magnificent group of buildings. The added attendance made possible by use of the trucks has provided the school with means to engage excellent instructors and to include new courses, which are a decided advantage to the pupils.

It may be added that the operating expense of the five vehicles is borne entirely by the union school district and not by the individual students. The five motor 'buses have been in constant service, making regular trips over the several routes each school day. Such work as has been necessary, apart from the daily inspection and adjustment in the school garage during the school hours, has been done on Saturdays.

At Corvina and Huntington Beach, in the same state, the towns have united the school districts for high school education and have purchased motor truck chassis equipped with omnibuses bodies, which are

The Latest Motor Omnibus Designed for Carrying the Scholars of the Fullerton, Cal., Union High School to and from Their Homes—The District Owns and Uses Five of These Machines.

used during the days the schools are in session. Here the 'buses are also driven by school pupils, who cover specified routes daily, taking the pupils from their homes to the schools and from the schools to their homes, making the trips on schedule and insuring attendance. The omnibus that is illustrated is in use at Corvina, where the machine makes a circuit of 12 miles four times each day, taking the scholars from their homes in the morning to the school, to their homes for lunch, and repeating this in the afternoon. The trucks are available for taking the scholars to different school functions, and at other periods of the day are used by the school boards for other work that may be necessary.

The work on the machines is largely done by the school boys, and the cost of operation is much less than were they driven by regularly employed drivers. One school principal believes that the machines are as essential to the success of the schools as are the libraries, and maintains that without them the attendance would be such that the schools could not be maintained as they are now. The machine shown in the illustration is a Moore chassis, made by the Pacific Metal Products Company at Torrence, Cal., fitted with

The Type of Moore Chassis and Omnibus Body Used by the Corvina and Huntington Beach, Cal., Union High School Districts for Transporting Pupils.

a body that may be enclosed with curtains in the event of storm. A similar machine is used at Huntington Beach.

The Globe Iron Works at Sacramento, Cal., has been purchased by the Lincoln Motor Truck Company, which will, when the equipment has been installed, begin the production of 1000 and 1500-pound delivery wagons. The general offices and the sales department will be located at San Francisco.

B. M. Beedon, who was associated with the Firestone Tire & Rubber Company and the American Voiturette Company, has been appointed a travelling representative for the Standard Motor Truck Company, Detroit, Mich.

The Lincoln Motor Truck Company of Los Angeles, Cal., is making overtures to business men of Sacramento, that state, for the location of its plant in that city. The company as yet is being promoted.

NEW ORLEANS ELECTRIC "BOOSTERS".

The Electric Vehicle Association of New Orleans, La., was organized at a recent meeting of men interested in the promotion of the use of electric vehicles in that city, which will be devoted to generally interesting the people in the value of these machines for all practical purposes, without reference to any particular make of equipment. The proposition was made to those in any way connected with electric vehicle or equipment selling and at a gathering at the De Soto Hotel, attended by 28 persons, the association was formed with T. C. Rhodes as president and W. E. Clement secretary. The president was authorized to appoint an executive committee of seven that will pass upon all matters.

The organization of the association primarily resulted from the endeavors of the representatives of electric vehicle and electric equipment manufacturers who are located in or visit New Orleans frequently, who are interested in the education of the people in electrical transportation, and believe that united endeavor in this work is essential to material progress, being willing to establish business competition on the sane basis of quality and merit, represented without criticism of other products. In other words, they are united for constructive development and condemn destructive selling methods.

Among those who spoke at the meeting for organization were: C. W. Bell of the Electric Storage Battery Company, A. D. Stevenson of the Edison Storage Battery Company, and H. J. Myers, Jr., of the Baker Motor Vehicle Company. Mr. Bell described the activities of the Philadelphia section of the Electric Vehicle Association of America as an example of possibilities of united activities, and he proposed that an educational advertising campaign be inaugurated and continued systematically.

ALL VEHICLES LIGHTED IN NEW YORK.

An amendment to the highway law of New York State provides that all horse drawn vehicles in use on the highways, unless loaded with hay, shall carry lights at night, provided that they are in use outside of large cities where the street lights are not more than 500 feet apart. This provision, however, is expected to insure that practically all vehicles on the roads at night shall carry lights, and is regarded as a distinct advance toward making traffic safer in the country sections.

J. S. Dowling has taken charge of the plant of the Brantford Motor Truck Company, Ltd., Brantford, Ont., which has been declared bankrupt, and his purpose is to manufacture the material in stock and to continue the company as a going concern. The liabilities of the company are \$67,941.93, and the assets are \$57,236.32.

CONTROL REAR AXLE PATENTS.

The Kardo Company has been organized at Cleveland, O., with capital of \$1,500,000, with Alvan Macaulay, vice president and general manager of the Packard Motor Car Company, as president; T. W. Frech of the Peerless Motor Car Company as vice president, F. C. Dorn of the American Ball Bearing Company as secretary and treasurer, and with Milton Tibbetts, F. S. Perry and Walter C. Baker, representing the Packard, Peerless and American Ball Bearing companies respectively, as directors. The company controls a series of patents issued to W. C. Baker, Hopewell, Charles T. C. Sangster, Alanson P. Brush, Charles Schmidt and various reissues, covering anti-friction bearings in front axles, rear axles on removable pinion mounting, adjustment of bevel gears, rear axle construction, bevel gear driven and compensating mechanism, adjustment of bevel gearing, rear axle transmission, etc., which are owned or controlled by the three companies concerned. With a view of eliminating possibility of conflict or controversy the company was projected and organized. The company has issued licenses to manufacture under its patents, and it is understood that it will continue this policy.

"SETBACK" BY UTTERBACK.

When the city council of Des Moines, Ia., enacted an ordinance that prohibited an automobile standing at a curbing more than 20 minutes, there was rejoicing by those who did not own vehicles, and consternation followed when the police arrested a number of citizens who sinned to the extent of a few minutes. The defendants appeared before Judge Utterback in the police court, who discharged them, claiming that as he interpreted the law the legislature did not delegate to the city council the authority to specify what period of time a car should be left standing at a street curbing. Now the citizens who own machines have somewhat regained their composure and the advocates of the ordinance are correspondingly depressed.

ELECTRIC WAGON ON RUNNERS.**Interesting Experiments by Hartford Engineer During Snow Blockade.**

The heavy snow storms of February accumulated more than 18 inches of "the beautiful" in the streets of Hartford, Conn., and as this was on a level the additions from sidewalk paths and from the car track plowing added considerably to the depth of the normal precipitation. In all the streets not plowed by the street railway company haulage was done with extreme difficulty for a considerable period of time, and the experience with motor vehicles was that the snow would not permit sufficient traction to make good headway, especially where the streets had not been plowed.

All vehicles that were propelled by the rear wheels, when driven into deep snow, especially if the depth was such that it reached the dust pans or the running boards, were held above the ground and the snow afforded but little traction, even with chains. In many instances the snow was pushed along until the body "rode" it, and the rear wheels were gradually lifted free and revolved without result.

Willis M. Thayer, manager of vehicle sales of the Hartford Electric Light Company, whose company is agent for General Vehicle electric machines, made some decidedly interesting experiments with runners attached to an electric wagon, and while he did not work out what he believes to be ideal equipment, he is of the opinion that with the results obtained he can build what will be in every way practical for use in such conditions as obtained in Hartford.

The machine was a one-ton wagon with an under-slung battery box, which has a clearance of about 11 inches, and this was found to push the snow ahead of it when the rear wheels had traction, although the weight was such as to prevent the wagon "riding" the packed snow to the same extent as might have been experienced with a vehicle with dust pan and running boards. With a view of carrying the front wheels on

Using an Electric Wagon with Sleds in Deep Snow, an Experiment Made at Hartford, Conn.: At Left, the Runners Under the Battery Box Are Shown, and at Right the Arrangement of the Forward Sled, Which Was Turned by the Hand Wheel and Steered the Machine Equally as Well as When Running on Wheels.

top of the snow, a "bob" was constructed that was attached between the front wheels, and so coupled that it could be turned with the steering wheel, the weight of the wagon being carried on this. The sled or set of runners was a frame with shoes about 2.5 inches wide and perhaps four feet length, the frames being braced with cross members and rods. A second set of runners was built and attached rigidly under the battery box.

The outfit was tested in deep snow and the forward construction was found to be in every way practical, although the runners ought to be further apart. The runners were apparently of sufficient area to support the forward end of the wagon, for one of the accompanying illustrations is from a photograph made where the snow was at least a foot deep and the wheels are carried well above the surface. With this the wagon steered perfectly and was steady and dependable so far as control was concerned.

The experience with the runners under the battery box was that they were too far forward and too narrow. Being firmly attached, when deep snow was reached the runners mounted on the surface if it were hard, or did not sufficiently support the machine if the snow was soft. Careful observation and numerous tests convinced Mr. Thayer that it would be practical to mount a rear sled with wider runners further back and on springs, so that while the runners would partially support the battery the rear wheels would sink sufficiently into the snow to afford traction.

As arranged the front sled was so mounted that the runners cleared the surface about two inches when the wagon was running on its wheels, and the runners under the battery box were designed to have about the same clearance. Mounted on the rear axle they would probably require more clearance, possibly four or five inches, but the results with such installation were not determined because of lack of time. Mr. Thayer believes that the use of runners is thoroughly practicable and that with such adaptation the trucks could be driven in exceedingly deep snow.

TRUCKS IN TELEPHONE SERVICE.

The Bell Telephone Company, Philadelphia, Penn., has taken delivery of three White 3000-pound wagons that are equipped with bodies suited for the use of its construction department. The company now has 24 White machines in its service, two of which are five-ton trucks equipped with double-power winches, which are used for hauling cable through conduits. When this order was filled a delivery of three machines was made to the Southern Bell Telephone Company.

The Mogul Motor Truck Company has been organized at St. Louis, Mo., under the Missouri law, with capital of \$100,000, by George C. Griffith, P. R. Walsh, Julius Berninghaus, C. S. Cobb, J. T. Hick and George W. Hunter.

S. A. E. COMMITTEES.

The following division chairmen have been appointed by the chairman of the standards committee of the Society of Automobile Engineers, Henry Souther, and these executives will arrange the meetings of the groups during the coming year: Aluminum and copper alloys division, William H. Barr, Lumen Bearing Company; ball and roller bearings division, Howard Marmon, Nordyke & Marmon Company; broaches division, C. W. Spicer, Spicer Manufacturing Company; carburetor fitting division, G. G. Behn, Hudson Motor Car Company; commercial car wheels division, William P. Kennedy, consulting engineer; data sheet division, B. D. Gray, Hess-Bright Manufacturing Company; electrical equipment division, A. L. Riker, Locomobile Company of America; electric vehicle division, J. R. Coleman, Atterbury Motor Car Company; frame division, J. G. Perrin, Lozier Motor Company; iron and steel division, Henry Souther; lock washer division, J. E. Wilson, National Lock Washer Company; miscellaneous division, J. G. Utz, Perfection Spring Company; motor testing division, J. O. Heinze, Northway Motor & Manufacturing Company; nomenclature division, Arthur B. Cumner, consulting engineer; pleasure car wheels division, Henry Souther, consulting engineer; research division, David L. Gallup, Worcester Polytechnic Institute; seamless steel tubes division, H. W. Alden, Timken-Detroit Axle Company; springs division, Harold L. Pope, Pope Manufacturing Company; truck standards division, William P. Kennedy, consulting engineer.

The following meetings of the divisions have been announced: Iron and steel division, March 10; springs division, March 17; broaches division, March 24; electric vehicle division, March 31; standards committee, April 7-9; research division, April 21; electrical equipment division, May 5; ball and roller bearings division, May 12; motor testing division, May 14.

A branch of the General Vehicle Company has been established at 327 Main street, Springfield, Mass., which is in charge of Preston T. Miller as manager. The interest in electric vehicles in that city and vicinity has impelled the company to have direct representation there.

The Lawter Tractor Company has been incorporated at St. Marys, O., with capital of \$125,000, to manufacture motors and power propelled machines of all kinds. The incorporators are L. C. Meeley, A. Herzog, H. E. Jennings, O. Carpenter and Hobart Scott.

The Irwin Motor Truck Company has been incorporated with capital of \$500,000 by Murray Irwin, who was sales manager of the Lewis Spring & Axle Company, and the purpose is to establish a factory at Marshall, Mich.

THE FARR TRUCK TRANSMISSION GEARSET.

A PATENT has been granted to Herman G. Farr, a mechanical engineer of Springfield, Mass., who has assigned this to the Knox Automobile Company, which covers the construction of a motor vehicle power transmission gearset, designed for use with machines built for freight service. The gearset is a conventional type with sliding gears that may be selected at will so as to afford any desired speed ratio, but as designed it is intended for incorporation with a differential casing such as is constructed for the jackshaft of the chain driven machine, and assumedly is not combined with rear axles of the floating construction.

The gearset and differential casing are divided longitudinally, the lower section carrying the gearset and the differential gearing, the upper portion being practically a cover. The gearset itself is built with the main shaft and the countershaft paralleling at the same height, with the reverse stud shaft carried below, the main shaft carrying the movable gears, which are coupled by dog clutches. The gearset does not differ in the constructional details from the conventional type up to this point, but instead of the bearings carrying the shafts being mounted in the end walls of the casing the case carries a frame in which the entire gearset, including the pinion shaft, is mounted. This frame or cage is in two parts and is bolted together at a point near the centre, the frame members being substantial in construction and designed to endure under heavy stresses.

The ends or head members of the frame are fitted accurately into the casing, so that the gearset as an assembly is rigidly supported, and these are retained in the case by substantial studs that are inserted externally through the case. When assembled the frame is practically a part of the case, but by the removal of the cover of the case and the retaining bolts the frame with the shafts, bearings, gears and pinions may be removed from the casing. The value of the construction is that with comparatively little labor the gearset may be taken from the case for examination, and it may be placed on a bench practically operable, when it can be tested, and if repair is necessary it can be assembled and tried before being placed in the casing.

The removal of the gearset as an assembly is known to be a decided saving in labor, as well as an insurance that it is operative, while all parts can be worked on with much greater ease and rapidity while on a bench than in the vehicle. The clearing of the case of the gearset also makes practical and easier the work that may be necessary with the differential, so that this need not be removed save for repair, as adjustment can be easily made, and the casing can be completely cleaned without much labor and with assurance that the gearset will be in perfect condition when restored to the case. The removal of the cover

section of the case affords the same access that is had with the ordinary construction, and should there be need the gearset may be taken out with comparative ease.

In the drawings reproduced, a is the gearset and differential case, b the differential, c the extension of the rear head to support the main shaft bearing, d the bevel gear of the jackshaft, e and f the head members of the gearset frame, g and h the supporting members for the gear shifting rods, i and j the gear shifting rods, k the main shaft, l the countershaft, m the reverse stud shaft, n and o the gear clutches, n' the frame or cage connection flanges, and r the frame or cage. The accompanying illustration of the gearset is very comprehensive, as it gives the detail of construction clearly. The top or plan view is of the gearset assembled in the case and as a unit with the differential gearing, for the removal of the cover exposes every part of the assembly, and the end or frame mem-

The Farr Transmission Gearset: At Left, Plan View, Showing Combination with Differential; at Right, Top, Longitudinal Section at the Figures 2—2; Bottom, Transverse Section at the Figures 3—3.

bers that contain the gearset can be noted as supplying the conventional solid ends of the casing. Aside from this sectional design the case conforms to ordinary construction. Turning to the upper right sketch in the illustration it will be noted that this is a vertical longitudinal section, at the points designed as 2—2 in the plan view, and this indicates the end members and the stud bolts retaining them, as well as the flanges of the frame, which are bolted together directly over and under the gear, the flanges forming a web that materially stiffen the frame when assembled. It will be seen that the end members are heavily constructed and intended to endure hard service. The lower right sketch is a transverse section at the flanges of the frame, at the point indicated in the plan view as 3—3, this indicating the relative positions of the shafts and gears.

New agents for the Koehler ton delivery wagons are D. H. Haskins, Newburn, N. C.; Hanover Street garage, Manchester, N. H.; H. Curtis Krout, New Freedom, Penn., and Cochran & Co., Cincinnati, O.

TRUCK IS "BEST INVESTMENT".

Striking Economy of Motor Vehicle in Wholesale Paper Distribution.

A remarkable instance of efficiency and economy is afforded by the experience of the J. & F. B. Garrett Company, Syracuse, N. Y., wholesale dealer in paper and printers' supplies, which has for a considerable length of time used a Palmer-Moore 1600-pound delivery wagon in its city delivery. Syracuse has a population of about 150,000, and it is the commercial centre of a large section of central New York State. Some portions of the city are well elevated and many of the streets have long grades, while at certain periods of the year the unpaved streets are deep with mud, these conditions making haulage with animals somewhat more expensive than might be assumed.

The J. & F. B. Garrett Company makes distribution throughout the city and into the suburbs, and had maintained its own delivery service until last year, when the motor wagon was purchased. During the past winter more snow fell in New York State than for 30 years, and this condition tested the machine to an unusual degree, as for weeks the streets were deep with snow and delivery was made without unusual effort. In February, in response to a request for an opinion as to the results that had been obtained with the machine, the president of the company stated, "Our truck is the best investment we have ever made".

In connection with this, the statement was made that the experience of the company had absolutely convinced it of the desirability of motor vehicle delivery, and, upon reflection, that the company had continued with horse vehicles as long as it did was a source of wonder. By this was meant that economy of the motor delivery wagon was considered established beyond question. Up to that time the upkeep

cost of the machine, including the driver's wages, was but \$1 a week more than had been expended for a single unit of the horse delivery, including the salary of the driver.

But the machine was used to do the work of two and sometimes three horse wagons, and while the goods are bulky and not easy to handle, a load will average 1200 pounds, and the average day's driving is approximately 40 miles. An example of possibilities with a machine is cited in making 18 deliveries after 4 in the afternoon, which was easily done despite adverse conditions.

ROBERTS SELLS STANDARDS.

The Standard Motor Truck Company of Ohio, maker of Standard delivery wagons, with factories at Warren, O., and executive offices at Cleveland, O., has appointed W. M. Roberts, formerly general sales manager for the Stewart Iron Works Company of Cincinnati, O., as general sales manager, and he will supervise all sales in this country and abroad. He has established headquarters at the Cleveland office.

The Standard machines are made in 2000, 3000 and 4000-pound sizes and are to be produced in large numbers as soon as the additions to the Warren factories, which will provide for an increase of 400 per cent. in production, are completed. The plans for the new buildings have been accepted and the work is now in progress.

NOVEL TIME PAYMENT PLAN.

The Gerlinger Motor Car Company, Portland, Ore., which has branches in several cities in Washington and Oregon, has developed a plan for time payments which it is maintained will be satisfactory and work out to the benefit of all concerned. This applies

to all of the agents for the company who sell trucks on time payments, receiving notes for the balance remaining unpaid. Instead of the agents holding the notes these are purchased by the Gerlinger Motor Car Company, charging for this a nominal amount. Thus the company holds notes that are made payable to the sub-agents, instead of holding them as direct payments, the benefit being that the sub-agent can deal with those who wish to make time payments and need not himself invest his own capital. This plan is said to greatly increase the sub-agents' opportunities for business.

Palmer-Moore 1600-Pound Delivery Wagon, with Four-Post Body and Air-Cooled Motor. Used in City Work by the J. & F. B. Garrett Company, Syracuse, N. Y.

ELECTRIC COMMERCIAL VEHICLE TIRES.

"ELECTRIC Commercial Vehicle Tires" was the title of a paper, illustrated by curves and diagrams shown on a screen, which was read by F. R. Whitney to the members of the Electric Vehicle Association of America the evening of Feb. 24, at the headquarters of the organization in the United Engineering Societies' building, 29 West 39th street, New York City. Mr. Whitney is chief engineer of the Commercial Truck Company of America of Philadelphia, and he has devoted much study to the subject of tires and their influence on vehicle service. Few men have made as careful investigation of this subject as he, and his observations have been noted with extreme care.

Naturally, the paper was given over to consideration of the solid or band and block types used for service vehicles, and pneumatic shoes were only referred to incidentally or for comparisons only, and should not be understood as being the subject of his tests or experiments. Mr. Whitney has devised instruments for tire testing and his experience has extended over a considerable period of time, so his conclusions may be regarded as being fundamentally sound and not with a view of favoring any particular type. Mr. Whitney's paper was in part:

The principal causes of the recent rapid rise in popularity of electric vehicles has been due to the fitness of the electric vehicle for city work and to marked improvement in essential features as ball and roller bearings instead of plain; batteries with largely increased capacity and reduced weight; reduced maintenance cost; reduced cost of electricity and increase in number of charging stations; better and more efficient motors and types of gearing; and last, but not least, greatly increased tire life and, in addition, increased effective quality of the rubber.

Items Affecting Operation Cont.

The items affecting the cost of operation of electric vehicles have within the last 10 years undergone changes approximately as follows:

Battery—Weight reduced, 30 per cent.; capacity increased, 25 per cent.; life increased, 50 to 150 per cent. **Tires**—Life increased, 100 per cent.; cost reduced, 50 per cent. **Mechanical parts**—Life increased, 100 to 500 per cent.; transmission, gearing, bearings, etc., weight reduced, 30 to 50 per cent.; efficiency increased, 50 per cent. **Current rates**—Reduced, 50 to 75 per cent.

The purpose of this paper is to briefly outline several interesting features noted in studying the tire question and the consequent effect on the performance of the vehicle. The prevailing types now on the market can be divided into two distinct types, viz., endless and block, and further sub-divided into five classes.

There are reasonable arguments as to the advantages of each class, and as all classes are in general use, there must be merit in each, the general drift at the present time, however, seems to favor the hard rubber base tire.

Points to Be Considered.

In selecting tires best suited for any particular case, there are five points to be considered from the point of view of the electric vehicle user, and I place them in the following order: First, efficiency; second, durability; third, resiliency; fourth, weight; fifth, cost.

With tires, the most efficient is the one that will roll along the road and offer the least resistance to rolling. A well designed truck with good tires will show a current consumption of say 35 watts per 1000-pound mile, and of this total of 35 watts from 20 to 25 are absorbed in the tires alone, leaving the remaining 15 to 20 distributed between bearings, gearing, motor loss, windage, etc. A change in tires on this same truck could easily increase the current consumption to 50 watts per 1000-pound mile, or in comparison in miles on one charge of the battery the truck in the first case would cover say 50 miles on one charge of the battery as against 35 in the second case.

Methods of Efficiency Test.

Several methods of efficiency test which have been found most satisfactory are as follows:

First, bounce test, which consists in dropping a piece of hard material on the tire from a definite height and measuring the height it will rebound. The proportion of the rebound to

the total height will represent the efficiency of the tire, and although this is simply a comparative test, the results secured have been reasonably accurate and the test is quickly taken with tires either on or off the wheel.

Second, coasting test, allowing the vehicle to coast down a known grade and determine the distance it will run, this being repeated with different makes of tires; the more efficient tire will coast farther. This test involves changing wheels and to be accurate should be repeated under identical conditions and one test should follow the other as closely as possible.

Third, running test, which is made by running the vehicle over a measured course and with proper instruments and stop watch determine the power consumed in terms of watt-hours per ton or 1000-pound mile.

Fourth, towing test, with traction dynamometer. This consists in towing the vehicle over a definite course in both directions and observing the draw bar pull required. This is an accurate test and easily taken, but has the disadvantage of requiring the second vehicle and more men.

Fifth, dynamometer test, which consists in mounting the tire to be tested and rolling it against a steel tired wheel, the resistance to rolling being determined in pounds at various speeds and pressures.

Mr. Whitney illustrated these tests by elaborately plotted curves showing results. From them he concluded that a vehicle equipped with one specified tire would cover, say, 50 miles on one charge of the battery, whereas a vehicle equipped with another indicated, over the same route and using the same battery equipment, would be able to cover only 30 to 35 miles. He continued:

The question of durability is important, as the cost of laying up a truck to have tire changes made involves considerable expense as well as inconveniences. For this reason a high priced tire that will run 10,000 miles is a decidedly better proposition than a tire costing 20 per cent. less which will only give 8000 miles of service.

Value of Resiliency.

Resiliency is frequently used as referring to tire efficiency and indicates the amount the tire will depress under a given load, and its value is in the cushioning effect. The amount of cushion which the tire interposes between the wheel and the road is an important factor in the value of the tire as measuring the amount of injurious vibration and shocks which are absorbed.

It is interesting to note that usually the first idea is that the heel of the blocks is worn out first, but, as a matter of fact, the toe is worn more on account of its creeping out from under the load as the wheel revolves. It is frequently contended that block tires eliminate the wave in front and consequently are more efficient than endless tires. This is a fallacy, however, as the wave, instead of being continuous, is broken by each block, and very careful tests for efficiency have shown conclusively that with rubber of the same compound the efficiency test is the same.

Importance of Weight.

The question of weight is usually given consideration by the vehicle manufacturer, but the tire manufacturer and the user do not seem to appreciate the importance of reduction in weight, as is evidenced by the fact that practically all of the tire manufacturers in producing their hard base designs have applied an intermediate band to the wheel simply for the purpose of securing the tire, although the added weight from this band on a set of wheels for a five-ton truck amounts to approximately 400 pounds, and the cost of hauling this 400 pounds—which is approximately 2.5 per cent. of the weight of the truck carrying average load—around for one year amounts to \$40, which figure is arrived at by taking the cost of tires, battery and current for one year, so that no further argument is needed to emphasize the importance of keeping the tire weight down and eliminating all unnecessary weight in the attachments.

The cost of tires should not be taken as the controlling factor, as 10 or 20 per cent. difference in tire cost can easily be offset in other items of expense.

Tests made to determine the effect of temperature upon tire efficiency show that the efficiency is materially reduced in dropping from 100 degrees to 50 degrees. Observations made on this point show that taking a cold tire, which will test, say, 50, and after giving it a number of hammer blows in the same place, the same tire will test several points higher, although the temperature has not been materially increased.

The Hearsey-Willis Company, Indianapolis, Ind., has been named as the selling agent for New Departure ball bearings for the central section of Indiana, and will carry a considerable stock of all types at its place of business.

FEDERAL ROAD SUPERVISION.

Government Officials and Highway Contractors to Select Route to Develop.

The federal government is not committed to any policy with reference to the improvement of highways, and up to the present time Congress has made no appropriation for road development, aside from that necessary in the administration of the federal districts of Alaska or Columbia. The office of public roads of the Department of Agriculture was created with a view of collating and supplying information that might be of interest to state and municipal road builders. In connection with this limited experimental work has been done for a number of years.

Several bills have been introduced into Congress providing for national aid in road development, but these have generally provided for appropriations. No federal policy has been established with reference to highway building, and the policies of the different states have not been defined. The different national and state bodies devoted to the promotion of road development are generally united as to purpose, but are widely apart so far as engineering, use of materials, supervision, maintenance and other details are concerned. Strangely enough no real system has ever been determined with reference to these essential factors.

The first move that will lead to a concentration of policy and endeavor was inaugurated recently when a party of representatives of the office of public roads and officials of the American Highway Association and from the highway departments of several states was driven from Washington to Atlanta, Ga., over a route which was selected with a view of systematically improving it under the supervision of engineers attached to the office of public roads.

The purpose of the offer of federal supervision is to demonstrate to the states, counties, towns and cities through which the route is laid out, the value of uniform construction and maintenance, and to determine the merit of standards that have been tentatively adopted by the office in its advisory relations with the people. The belief is that co-operation of the federal and state officials can lead to uniformity of road improvement, and the purpose of having the work cover a distance of approximately 850 miles is to show that the policy can be applied to road building in general and to deal with as varied character of construction and maintenance as is possible.

The activity of the office of public roads resulted from a conference of Director Logan Waller Page, Chairman Leonard Tufts of the special committee of the American Highway Association, that had been appointed by the organization to promote the work, and Executive Secretary J. E. Pennypacker of the association, and the determination of Mr. Page to assign three of the best engineers of his department to super-

vise the highways included in the route. But their service was conditional upon the American Highway Association securing the co-operation of the highway departments of the different states. The state officials were enthusiastic when conferred with and their advocacy determined the proposition. While not definitely decided, one engineer will probably have oversight of the work from Washington across the District of Columbia and Virginia to the North Carolina line, the second the work in North Carolina, and the third the work in South Carolina and Georgia.

The officers of the American Highway Association maintain that substantial demonstration will have very large practical value, and will bring more beneficial results than theoretical stimulation, but this will be applied more to the section of the country in which the route is located. Of course time will be necessary to determine the results. The association has arranged for automobiles being placed at the command of the officers who shall supervise the roads, that they may have the means of reaching whatever section may be necessary.

The party that first drove over the roads to be dealt with included Capt. P. St. J. Wilson, assistant director of the office of public roads; Mr. Tufts, Mr. Pennypacker and the representatives of the highway departments of Virginia, North Carolina, South Carolina and Georgia. Where desirable, meetings were arranged with citizens and local officials, and plans made for the surrender of the control of the roads during the time of supervision and the expenditure of the available funds under the direction of the engineers. While locality policies have been encountered, the belief exists that with the assurance that the government officers will wisely and practically expend the money ordinarily raised for improvement, and the fact that the roads will be the subject of national interest, interested co-operation will be given by all committees.

The Whitford Corporation, with capital of \$25,000, has been incorporated at Woodport, N. Y., by Charles E. Whitford and Charles S. Gaywood of Weedsport and Thomas M. Osborne of Auburn, N. Y., for the purpose of manufacturing motor trucks.

Peacock Bros., 2841 Broadway, Oakland, Cal.; C. C. Misner, 15 Kentucky street, Petaluma, Cal., and C. E. Shannon, 125 Mill street, Rochester, N. Y., have been made agents for the Adams Bros. Company, Findlay, O., maker of the Adams trucks.

Motor truck bodies will be the specialized production of the Bee Automobile Company, Allentown, Penn., which was recently established by Reuben H. Bachman, Peter Bradbury and Francis Bachman.

D. R. Harrington has resigned from the Universal Motor Truck Company, Detroit, Mich., and has associated himself with the International Cyclecar Company.

STREET CLEANING COST IS DECREASING.

Reports from London and Chicago Indicate Important Effect of Wider Use of Automobiles and Trucks---News in the Municipal Service Vehicle Field.

IT WAS shown recently in these columns, by analysis of the figures given in the official report of the commissioner of public works and the civil service commission of Chicago, that the substitution of motor vehicles for all the horse drawn wagons in use in that city would result in a saving of \$1,000,000 a year in street cleaning expense alone. Attention is drawn to this situation by the National Automobile Chamber of Commerce, commercial vehicle section, in reviewing figures made public respecting street cleaning costs in London, England, as a result of the decrease in horse drawn vehicles and the abandonment of water bound macadam pavement.

The official table of reductions in street cleaning expense (translated from pounds to dollars), which have occurred in six years in half a dozen large boroughs in London, is published as convincing proof of these statements by a writer in the Pall Mall Gazette, a copy of which was brought to this country recently by John A. Wilson, president of the American Automobile Association. The table follows:

Cost of Street Cleaning in London.

Borough	1905-6	1911-12	Decrease a Mile
Battersea	\$144,350	\$105,765	\$540
Chelsea	69,435	53,850	540
Fulham	85,285	60,720	530
Paddington	151,785	114,855	620
Westminster	433,700	345,120	895
Wadsworth	221,930	159,460	470

Decreases were reported in 17 other boroughs, and it was shown that it cost an average of \$1700 a mile for street cleaning in 1905-6 as compared with \$1480 in 1911-12, a saving of \$220 a mile on 2154 miles of streets, or an aggregate of \$473,800 annually.

Corroborative evidence that the cost of street cleaning is decreasing is found in the records of the Citizens' Street Cleaning Bureau of Chicago, an organization made up of property owners and business men in the First ward. The bureau is engaged in cleaning streets and alleys, flushing, sprinkling, snow removal, cleaning catch basins and removing ashes in the loop district. It cleans approximately 119,000 square yards of streets and 20,000 square yards of alleys. The figures presented in a table below show how the cost of cleaning streets has decreased steadily during the six years from 1907 to 1912:

Some very interesting deductions may be made from a study of the table. It will be noted that there has been an actual decrease of more than \$12,000 a year in the cost of sweeping

and removing refuse, although the expense for the alleys has increased. It may be added that the cost of snow removal has more than doubled, from \$11,343 to \$24,430 a year, while that of sprinkling has been increased from \$640 to \$6464 a year. The total in question follows:

Cost of Street Cleaning in First Ward, Chicago.

Year	Cleaning		Carting		Totals
	Streets	Alleys	Streets	Alleys	
1907	\$39,767	\$3581	\$7756	\$1457	\$52,561
1908	33,942	3404	7501	1830	46,677
1909	31,865	3379	7620	1687	44,551
1911	30,370	3450	5936	766	40,522
1910	31,531	2917	7674	690	42,812
1912	29,172	3485	6399	813	39,869

PEERLESS FIRE APPARATUS.

The city officials of Cleveland, O., recently expended \$100,000 in equipping the fire department with motorized apparatus, made by the Peerless Motor Car Company of that city. Included among these vehicles was a rebuilt steam fire engine, the Peerless company utilizing the old boiler, pump, etc., in remounting it on a regulation Peerless truck chassis.

This was decidedly in the nature of an experiment, but, in the opinion of Safety Director Benesch, who witnessed a demonstration of the rebuilt steamer, it is quite as efficient as the gasoline pumping engine which the department recently acquired, while the expense of making the change figured out at about half that paid for the other type of machine.

An accompanying illustration shows one of the new Peerless combination chemical engine and hose wagons at work at a recent fire. This type of machine has met with very ready acceptance, the Peerless company having installed a number in cities in Ohio, Illi-

Peerless Combination Hose and Chemical Wagon at Work on Recent Fire in Cleveland, O.

nois and Pennsylvania during the past few months. The company also makes a specialty of motorizing present horse drawn equipment of this character, thereby making a substantial saving to the municipality which may have serviceable equipment and desires to have it brought up-to-date.

MOTORS SAVE MONEY.

Mayor George M. Wright of Worcester, Mass., is an enthusiastic advocate of automobile equipment for municipal departments. He declares that they save money in each instance, to say nothing of the greater efficiency.

Worcester recently purchased and placed in service a new combination police patrol wagon and ambulance, made by the White Company, Cleveland, O., and four new motorcycles, for the police department; an American-La France hook and ladder truck for the fire department, and a Peerless five-ton truck fitted with a sprinkling apparatus for the street department.

Mayor Wright announces that the fire department has set aside sufficient money for the purchase of three more pieces of apparatus during the current year. He feels that no mistake has been made in selecting the American-La France truck, because the Panama-Pacific Exposition Company has ordered 12 pieces of apparatus of the same make for use during the world's fair in San Francisco in 1915.

He estimates that the new sprinkler will save not less than \$3000 for the street department this first year. It will be utilized for distributing oil and water on all streets and in new macadam work.

WELLESLEY COLLEGE FIRE.

The advantage of utilizing motor fire apparatus was particularly noticeable as a result of the recent fire which destroyed a large portion of the main building at Wellesley College, Wellesley, Mass. As the lo-

cal department was poorly equipped to handle a blaze of these proportions, aid was summoned from nearby towns and cities.

The City of Newton responded with its Knox pumping engine and a hook and ladder truck equipped with Knox-Martin tractor, both pieces having recently been supplied to that city by the Knox Automobile Company, Springfield, Mass. On account of confusion attendant at the fire the Newton department did not get the call until some time after the alarm had been sounded, but made a splendid run over the intervening six miles.

The pump was immediately coupled to a hydrant and worked steadily for over 3.5 hours, with two lines out, saving the right wing of the building. It was somewhat handicapped by lack of water, but in spite of this gave a handsome performance, making the first real hard test to which it had been subjected since its installation.

Apart from the demonstration of efficiency made by this vehicle, it is of interest to consider the possibilities for co-operation among cities and towns located near each other. Under similar circumstances, with equipment of this character it should prove entirely practicable for such towns to combine forces in the event of sudden need, so as to reduce the danger of conflagration to a decided minimum.

NEW YORK POLICE WAGONS.

Having proven to its entire satisfaction, by the experience of the past, that a medium capacity motor truck will save over twice its cost each year in police service, the New York City police department recently purchased 25 Willys-Utility 1500-pound wagons, fitted with patrol bodies. The sale was made through the R. & L. Company, New York distributor for these wagons, made by the Willys-Overland Company, Toledo, O.

One of the new patrols is shown herewith. They have special screen side bodies, mounted on a somewhat enlarged chassis. The regular wheelbase of 120 inches was increased to 144, and the interior provides seating accommodations for 12 people. These also is room for two persons on the driver's seat. The body dimensions are 110 inches length from the rear of the driver's seat, 70 inches height and 66 inches width inside. The rear entrance is 32 inches wide and the rear step 36 inches wide. The equipment includes curtains at the side and rear, a stretcher carried under the seat, dome light, siren horn, push pedal gong, oil side and tail lamps. The exte-

One of the 25 Patrol Wagons Recently Delivered to the New York City Police Department by the Willys-Overland Company.

rior finish is in green with the lettering in gold.

By advancing the governor, the speed is increased from 18 to 25 miles an hour. The motor has bore of 4.125 inches and stroke of 4.5. Axles are drop forged, with Timken bearings in the hubs. The tires are 36 by 4.5 inches, single in front and dual in the rear, pneumatics mounted on quick detachable rims. The gasoline capacity is 15 gallons.

According to John N. Willys, president of the Willys-Overland Company, the main reason why the New York department chose these vehicles, on which the company is now specializing, was the showing made by 13 Garford wagons of a similar capacity in that service during the past two years.

NEWS FROM VARIOUS CITIES.

Ten Whites in Baltimore—Among the municipal sales recently made by the White Company, Cleveland, O., is that of two three-ton chassis fitted with fire apparatus to the department in Baltimore, Md. This purchase gives the department in that city a total of 10 White machines.

Will Not Ask for Bids—The city officials of Syracuse, N. Y., have practically decided not to ask for bids for the purchasing of three pieces of automobile apparatus which it is intended to place in station No. 1. Fire chiefs in other cities have intimated to the Syracuse department that it is not practicable to select fire equipment in this manner, since it often becomes necessary to take a machine of inferior ability because of a slight difference in price. Chief Quigley desires first of all to secure a six-cylinder tractor capable of hauling the heavy truck up the steepest hill in Syracuse, under any condition.

White in Ashes Disposal—The street cleaning department in New York City has been experimenting with a White dumping truck, made by the White Company, Cleveland, O., in handling ashes. Thus far, it has been able to do the work formerly done by five single-horse carts.

For Icy Roads—Chief George P. Cahoon of the fire department in Swampscott, Mass., has evolved what he believes to be a satisfactory method of starting motor apparatus on roads that are covered with snow or ice. He uses strips of rope matting about 18 inches wide, which are carried in a neatly rolled package. When the wheels cannot secure traction, the strips are laid on the snow or ice, when the tires grip them nicely. It is stated that the plan has been

tried under the most severe conditions, even where the road has been covered with hard, smooth ice, and always with success.

KisselKar in Fall River—An accompanying illustration presents the new KisselKar 60 horsepower combination chemical engine and hose wagon, made by the Kissel Motor Car Company, Hartford, Wis., and recently installed with the fire department in Fall River, Mass. The equipment is in every way complete, including two chemical tanks, basket for chemical hose, hand extinguishers, axes, etc., and plenty of room is available for carrying fire hose and the crew.

Adds to Motor Fleet—The board of public works in Indianapolis, Ind., has bought 12 additional machines for municipal service. Two of these are three-ton Kelly trucks, to be equipped with portable asphalt repair plants for use by the street department. Two are Buick wagons, for use by the field corps of the engineering department. The other purchases include four Buick and four Ford runabouts, for the heads of departments and inspectors.

In the Market—The following cities are considering the purchase of motor fire apparatus: Anacortes, Wash.; North Tonawanda, N. Y.; North Adams, Mass., chemical engine and hose wagon; Helena, Mont., combination hose and chemical; Lebanon, Penn., Union Fire Engine Company No. 1; Batavia, Ill., town meeting April 21, to decide upon bond issue; Fort Worth, Tex., one piece of apparatus each year until department is completely motorized; San Jose, Cal.; Alameda, Cal., tractor for hook and ladder truck; Rome, N. Y.; Bridgeport, Conn., tractors for all horse drawn apparatus; Lenox, Mass., triple combination pump, chemical and hose car; Montreal, Que., 85-foot aerial ladder, two hose wagons, four tractors and salvage car; Fayetteville, Ark.; Holland, Mich.; Bristol, Penn.; Altoona, Penn., \$50,000 loan authorized; Glen Ridge, N. J., hook and ladder truck; Scranton, Penn., appropriation of \$38,000.

KisselKar 60 Horsepower Combination Chemical Engine and Hose Wagon, Recently Installed in Fall River, Mass.

RENAULT FOUR-WHEEL DRIVE TRACTOR.

**Interesting New Design Incorporating Features Demanded by French Military Requirements
---Motor Equipped Farming Implements Revealed at Recent Agricultural Exhibition.**

ALTHOUGH it cannot be held that front wheel driven trucks and trailers are entirely new, machines of this type having been on the market both in

cased by an aluminum housing forming an extension to the gearbox. The lower half of this housing is fixed and the upper half is readily detachable. The arrangement allows the whole of the coupling and clutch withdrawing mechanism to run in oil, and has already been employed on other Renault truck models for more than a year.

Naturally, the gearbox is of special type. It affords four speeds forward and reverse, comprising usual primary and secondary shafts. On the primary is a central crown wheel engaging with pinion mounted on a shaft in the same vertical plane, this latter transmitting power through a front and rear

propeller shaft to the respective axles. Each of the propeller shafts has a universal joint at each end. The axles are of the well known Renault design, comprising a one-piece forging with a central cradle, and with a cast steel cover on the driving end and a detachable aluminum cover on the other.

Front Wheel Drive.

The front axle is bored out to receive the driving shafts, and, as the front wheels must steer as well as drive, there is an enclosed universal joint on the end of the shaft, within the steering pivot, as shown herewith, in the smallest illustration. Since a differential lock is necessary, this is provided by means of a lever in the change speed sector, with connections passing through the gearbox, left and right, to the two differentials, one on either end of the front axle.

There are three hand levers, as indicated, that at the left being the differential lock, that in the centre the change speed, and on the outside, the hand brake. The change speed lever also engages the capstan drive, which is at the left of the chassis, as viewed from the rear. The capstan itself is mounted on a heavy

Renault Four-Wheel Drive Tractor and Two Trailers, Taking Part in the French Military Trials.

this country and abroad for a number of years, interest in them has been increased very materially of late, by reason of the prominence given them in the military trials in France last month. One of the newer designs is the Renault, made by Renault Freres, Billancourt, France, this having been built to comply with the army regulations, although in a general way it follows standard practise with this company.

The Renault pleasure car is well known in this country, and the truck bearing that name has been described fully in these columns. It is only necessary to state that the motor used in this newest vehicle is a four-cylinder unit, cast in pairs, with bore of 130 mm and stroke of 160 (5.1 by 6.29 inches). Cooling is by thermo-syphon, but instead of vanes on the flywheel and an air tight underpan, there is a fan at the back of the radiator, which is at the rear of the motor, as with all Renault machines, driven by belt running over a pulley just behind the flywheel. This fan is enclosed by an aluminum casing bolted to the rear of the dash, and has a central quick detachable cover to enable the driven pulley to be reached without taking down the entire casing. Louvers are cut in the rear portion of the bonnet, so that air can be drawn through the central radiator tubes, and a sheet metal V section guard is fitted between the rear cylinder and the cooler, so that the current of air going through the bonnet may be directed onto the central tubes and not onto the engine.

Clutch and Gearbox.

The clutch is of the inverted cone type, and there is a spring disc coupling between it and the gearbox. The whole of the mechanism between the two is en-

Universal Joint Arrangement in Renault Front Wheel Drive.

platform at the extreme rear, and is driven by shaft and enclosed worm gearing. In addition to the external contracting brake at the rear of the gearbox, there is an internal expanding brake in each of the four wheels.

Cast steel wheels are employed, these being fitted with solid twin tires, 1055 by 130 mm (41.5 by 5.5 inches). Provision also has been made for the attachment of tire chains by fitting a series of hooks at intervals on the inner face of the rim, which permit the chains to be hooked on quickly whenever it becomes necessary to use them over the soft ground.

Duplicate Steering Gear.

The steering gear is duplicated, of course. A worm on the steering column engages with a sector on a horizontal shaft, set just within the right frame member. This shaft has two worms, one of which engages with the sector carrying the lever arm for the front wheels, and the second with a corresponding sector and lever connected with the rear wheels. From these two points the control is exactly the same as on the ordinary models.

Suspension is by semi-elliptic springs, front and rear. Each of these has a sliding shackle at the rear, and is 5.5 inches wide. Towing hooks are fitted at the front of the chassis, and there is a quick action spring mounted coupling at the rear, and a very powerful sprag is hinged from the rear axle, in accordance with army requirements.

The largest illustration shows one of the Renault front drive tractors as fitted for competition in the military trials, hauling two trailers shod with steel tires. Aside from the Renault, the makes represented in this year's trials were: Panhard, Balachowsky et Caire, Blum-Latil, Schneider and Aries. The Panhard has a Knight engine and the Balachowsky et Caire is a gasoline-electric machine. The results of the tests, which are to be worked out with extreme care, have not been made public as yet.

LIVERPOOL DOCK PROBLEMS.

The Liverpool Self-Propelled Traffic Association in England has been conducting an investigation with respect to the congestion existing at the docks and railway terminals in Liverpool, with a view to suggesting suitable remedies. It is stated that the number of motor vehicles in use at these places at present is comparatively negligible, and the investigators express as their opinion that under existing conditions of loading at the ship's side and unloading at the warehouse or railway depot, motor trucks as such are not a paying proposition. This is due to the necessary

time required in waiting, loading and unloading, which forms such a large proportion of the total daily time available that the high first cost vehicle is "swamped by standing charges" in more senses than one.

Experimenting with Trailers.

Inasmuch as the members of the association are convinced that the motor vehicle is capable of offering the proper solution of the problem, an opinion in which business men and terminal authorities agree, the object of the investigation was to discover some method by which these could be employed with satisfactory results. After experimentation, it was found that with a truck and four trailers, one with the truck, one loading, one unloading and a fourth in reserve, it was possible to handle nine or 10 six-ton loads a day, over a round trip of three miles. With this plan, however, it was found that there was some loss of time in manoeuvring the trailers.

The investigators held that were it possible to re-

Constructional Details of Renault Four-Wheel Drive Tractor: A, Differential Locking Lever; B, Change Speed Lever; C, Brake Lever; D, Foot Brake Adjustment; E, Fan Belt Drive; F, Enclosed Disc Universal; G, Rear Wheel Drive Rod; H, Steering Column.

duce the loading and unloading speeds to an average of six tons a quarter-hour, it would only be necessary to increase the travelling speed one mile an hour, in order to accomplish practically the same work. The advantages of this plan were held to be: Less congestion, fewer vehicles, ability to operate in confined spaces, less total gross tonnage moving on the roads and less cost for haulage.

Loaded Truck and Trailer.

A third method suggested calls for the combined use of a truck carrying a load on its own body, and a trailer. Under this plan, it would be necessary to provide such facilities that both vehicles could be loaded and unloaded simultaneously, in order to maintain the same average speed, although under such favorable conditions it would be possible to handle a greater tonnage in two-thirds the number of journeys and at a still further reduced cost.

As a result of these investigations, it is understood that a movement is on foot to put all three systems to a definite trial, in order that it may be determined just which one of the three presents the best results. In this experiment the association must receive the co-operation of the terminal authorities. At present there is some indecision as to whether the vehicles to be utilized in the experimentation shall be propelled by steam, gasoline or electricity, and it is not at all unlikely that all three will be given opportunity to make the test in comparison.

AGRICULTURAL EXHIBITION.

Whether or not it is because the agriculturists of Europe are forced to give greater consideration to the so-called intensified farming, as has been stated by prominent foreigners who have visited America, it seems true that more attention has been paid to the matter of motorized agricultural machinery on the Continent than elsewhere. About four years ago the motor plow first made its appearance at the National agricultural show in France. Progress has been somewhat rapid, as indicated by recent Paris display.

Farm machinery was exhibited in the Esplanade des Invalides, and practically all of the available space was utilized. The list of self-propelled implements included not only plows of every description, but hoes, planters, mowing machines, etc., and tractors of various types.

Some of the machines shown have been described fully in these columns. Among these were the Stock self-contained plow, made in Germany, and the Bauche hoe, made in France, both of which have enjoyed a wide sale on the Continent, and have only recently been introduced in Great Britain. America was represented in the show by the International Harvester Company's kerosene tractor and the tractors made by J. I. Case Threshing Machine Company.

Moto-Aratrice Plow.

One of the most interesting new machines was the Moto-Aratrice, produced by Pavesi Tolotti, 18, Via

Oglio, Milan, Italy. In this an entirely new principle is involved, in that the plowshares are pushed instead of being pulled. It is made in two models, one being rated at 16-20 horsepower and the other at 40-50. The accompanying illustration is that of the 16-20 horsepower machine.

The front of the vehicle is mounted on a single, pivoted steering wheel, which is arranged to be raised or lowered to give the desired depth of the furrow. The two-cylinder slow running motor is placed at the driver's left, who sits over the gearbox. At the outer end of the shaft extending through the gearbox is a sprocket from which final drive is by chain to the right rear wheel. In this wheel is incorporated an eccentric drum or hub, which operates 12 stout shafts connected at their outer ends to double-pronged blades pivoted between the side plates of the wheel. The eccentric action of the wheel in motion causes these blades to project in order to provide traction. After leaving the ground the eccentric action causes them to lie flat with the tread, until they pass the top centre.

The left rear wheel is said to follow the last share in the furrow, although this is not clearly indicated by the illustration. Provision is made for lowering or raising the frame at that point to keep the vehicle in a horizontal plane, and a brass indicator shows the amount of deflection and therefore the depth of the furrow. It will be noted that the three shares are carried on a frame extension securely riveted to the right main frame member.

Amiot Tractor-Plow.

Another interesting machine shown was the Amiot, made by Henri Amiot, 50, Rue Lesage, Rheims, France. This is termed a combined tractor-plow, in that the share frame can be removed and the remainder of the vehicle utilized as a tractor for various purposes about the farm. In many respects it differs decidedly from standard practise in this type of equipment.

The motor is a four-cylinder Abeille, mounted at the forward end under a hood, with the radiator in front and the fuel tank at the rear. This is rated at 40 horsepower. Drive is practically direct, there being only one speed either forward or backward, and power is transmitted to the 70-inch rear wheels by side chains.

A feature of the machine is the provision for turning the furrow either to the right or left, thereby making it unnecessary to go around the entire plot. A strong rigid frame at the rear carries six plowshares, three being above and three below, as shown in the accompanying illustration. Above this is a crane like girder, carrying a pulley at its outer end, over which is led a chain, by means of which the plowshare frame is hoisted and low-

Moto Aratrice, an Italian Machine Which Pushes Plowshares Forward Instead of Pulling Them.

ered from the driver's seat by the engine's power.

At the forward end of the plowshare frame is a train of gears, also operated by the motor, by means of which this frame may be rotated so as to bring either set of shares into action. This frame also is made detachable by removing two bolts. A yoke is then substituted, converting the forward portion of the machine into a tractor.

Plissonnier Mowing Machine.

Among the mowing machines shown was an entirely new model, produced by S. Plissonnier, 234, Cours Lafayette, Lyons, France. The construction involves the use of a long frame, with a 6-8 horsepower motor mounted at the front, over a single pivoted wheel. The fuel tank is carried on a light support directly over the radiator, feed being by gravity. Power is transmitted by cone clutch and a gear-set, affording but one speed forward and reverse, to the rear axle.

The operator is located well back of the rear axle, steering being by a vertical column, connected by suitable linkage to the pivoted front wheel. The cutter bar can be raised or lowered by a long lever at the operator's right, this being arranged to automatically engage a special clutch for placing the knives into and out of action. The appearance is very neat and the construction is such as to permit of easy operation.

GENERAL NEWS FROM ABROAD.

New British Dumping Wagon—As the result of the special attention which has been paid to the matter of quick unloading in Great Britain, the maker of the Bussing wagon has evolved a new body, the interior of which is made with sloping floor. The lower half of the side, on both sides, is made to let down, when the contents are discharged by gravity. This particular body was constructed upon order for a St. Petersburg firm.

Weight Limit in Germany—According to the *Zentralblatt der Bauverwaltung* (Board of Works Central Gazette), Berlin, Germany, the following prohibitions will shortly be imposed on freight automobiles and omnibuses: Metal tires, a heavier pressure upon the driving axle than two-thirds of the whole weight of the vehicle, a maximum weight exceeding 8200 kilos, speeds above 16 kilometers an hour (about 20 miles), trailers weighing more than 4000 kilos, wheels with a diameter under 75 centimeters (about two feet six inches). It is also proposed to remit a part of the automobile tax on vehicles with wheels of 90 centimeters (about three feet) in diameter, and unable, by their construction, to travel at more than 30 kilometers (about 19 miles) an hour.

Taxicabs in Germany—According to a recent report there were 4156 taxicabs in Germany, 2332 of which were operated in Berlin, 388 in Munich, 312 in Hamburg, 127 in Cologne, 110 in Hanover, 104 in Leipzig and 103 in Frankfort.

Automobile Show in Denmark—The first organized exhibition of automobiles of all classes held in Denmark will take place in Copenhagen, April 18-20. It is expected that it will prove of decided value to the American manufacturers who have applied for space.

Delivering Locomotive by Truck—In view of the growing competition between highway haulage and railroads, it is of interest to note that the Maudslay company in Great Britain recently was called upon to transport a railway locomotive by road, it being contended by the builder that the motor truck was able to deliver its product at its destination in less time than it would take by rail.

Motor Trucks in Persia—As yet there are but two motor trucks in Persia, according to Consul-General C. W. Wadsworth of Teheran, although it is expected that a demand will arise shortly as the result of road work now contemplated by the government. A tin of gasoline containing about 100 pounds costs \$9 in Teheran. The expense of shipping a car to Persia, including the Persian duty of 10 per cent., is estimated at \$300, and the time required from New York is given as three months.

City Buys Omnibus Service—Subject to the approval of Parliament, Birmingham, England, proposes to purchase from the Birmingham & Midland Motor Omnibus Company some 30 motor 'buses, its garage and plant for \$165,000. This purchase would give the city the monopoly of the motor omnibus service within its boundaries, under an agreement that, while through 'buses from outside points may be run by the company into the city and by the city into the country, neither is to pick up any but through passengers within the limits of the other's activities.

Amlot Combined Plow and Tractor, Indicating Novel Arrangement of Plowshare Frame.

New Commercial Car Accessories

Kramer Governor.

The B. G. Kramer Company, Milwaukee, Wis., is manufacturing the Kramer governor, which is especially for com-

mercial vehicles, where it is desired to limit their speed to a predetermined number of miles an hour. The device is also applicable to pleasure cars. The instrument is designed to control and maintain a constant speed of an internal combustion engine by governing the velocity of the incoming gases.

It comprises a throttle, connected to a disc member, that is allowed to float under a constant spring tension in a tapered conduit, the tension of the spring determining the maximum motor speed. Upon the velocity of the incoming gases changing, due to variation in engine speed, the position of the disc in the conduit is affected. This results in altering the position of the throttle, allowing more or less mixture, as the case may be, to be fed to the cylinders, and as the condition may require.

An auxiliary control lever is provided, permitting the driver to obtain any variation of speed up to the maximum afforded by the governor. It is pointed out that not only does the device make for efficiency and economy of fuel, but it cannot be tampered with.

Crown Prince Wheels.

The use of pressed steel in motor car construction is becoming more general and a new application of the material, at least in this country, is noted in the Crown Prince pressed steel wheels, which are being marketed by Max Bacham, 845 Jefferson avenue, East, Detroit.

It is held that they are 200 per cent. stronger than wooden members, lighter, and considerably more durable. It is also claimed that much more tire mileage is obtained and that greater speed is possible. One of the qualities of the design emphasized is that it will not collapse; merely bend when subjected to severe stresses which would break wooden constructions. Being of metal the Crown Prince design cannot shrink or the spokes become loose.

The Crown Prince is a demountable wheel, and it is stated that it may be removed and an extra member is easily fitted in about a minute's time.

Trio Filter.

The Trio Manufacturing Company, 1206 Bellevue avenue, Detroit, is marketing a combination sediment trap and gasoline reserve supply device which is intended to eliminate the necessity for carrying extra fuel. It is designed especially for those cars not equipped with auxiliary fuel tanks, and the maker states that the Trio not only insures a reserve supply of fuel, but makes a rigid tank connection.

It has a sediment trap to catch all foreign elements, and is also provided with a positive shut-off to the carburetor. A petcock at the bottom of the Trio permits of drawing fuel for priming purposes, etc.

The illustration shows the valve in a closed position. When the lever is

turned to a forward position the reserve supply is obtainable

Standard Auto-Thermo.

The Standard Thermometer Company, 65 Shirley street, Boston, is marketing the Standard auto-thermo, which is a neat, compact device fitted to the radiator cap and is adapted for attach-

ment to either the hinged or screw cap. It is fitted by boring a hole in the cap, inserting the extension and tightening a nut on the last named member. The part extending into the radiator actuates a hand which moves over a calibrated dial, the degree and direction of movement being influenced by the temperature of the fluid of the cooler, or, in other words, the motor.

The hand moves across transparent zones, and temperatures equalling that of freezing, maximum motor efficiency and steaming are shown. When the hand is in a vertical position, it indicates "Safe"; that is, the cooling water is at a temperature when the motor is operating at its maximum efficiency insofar as temperature is concerned.

R. O. C. Superheater.

The National Economic Supply Company, 1777 Broadway, New York City, is marketing the R. O. C. Superheater, a

device designed to raise the temperature of the fuel before it reaches the carburetor, and consequently, while it is in a liquid state. It is sprayed into the mixing chamber of the carburetor in the conventional manner but, as the gasoline is heated, it is obvious that it vaporizes readily.

The heat of the exhaust gases is utilized to raise the temperature of the fuel, the Superheater being connected in a branch line of the exhaust. The device is installed in the fuel line, consequently all gasoline passes through it before reaching the carburetor.

Stewart Carburetor.

The Detroit Lubricator Company, Detroit, manufacturing the Stewart carburetors, has developed a design for the model T Ford motor, which is held to be very efficient, easily installed, and to make use of the heat of the exhaust manifold. It is supplied either with thumb screw adjustment or to utilize the regular Ford dash adjusting rod.

The principle of operation of the Stewart is held to be entirely different from conventional types, and the maker states that the proportions of fuel and air are accurately determined, irrespective of the throttle opening. Use is made of a metering valve, which moves up and down, according to the suction of the motor, and it is held that the amount of fuel and air admitted to the mixing chamber increases or decreases in exactly the same ratio, obtaining the correct proportions at different speeds.

The lower end of the metering valve extends down into the gasoline and around a taper. Because of the decreasing diameter of this pin the higher the metering valve is lifted the larger will be the opening into the aspirating tube, and more fuel will be drawn up.

THE A B C OF MOTOR TRUCK IGNITION.

Part XX—Construction and Operation of Simms Independent and Dual Types of Magnetos Employing Pole Shoes with Extensions Which Are Held to Make for Maximum Efficiency--Features of Dual Switch.

By C. P. Shattuck.

ONE of the oldest manufacturers of magnetos for internal combustion engines is the Simms Magneto Company, East Orange, N. J., and the product

of the engine can be rotated manually only at a slow rate of speed.

Timing Range.

It is claimed that in the Simms instruments a spark of greater intensity is produced at a fully retarded position of the breaker mechanism than at fully advanced, because of the peculiarly constructed pole pieces. It is also stated that they prevent the possibility of injury from a back fire and that it is possible to start the motor on a quarter-turn, provided, however, the mixture is correct. As the spark is advanced with the corresponding increase in speed of the motor, it is stated that its intensity is maintained over the entire firing range up to the fully advanced position, when the spark is even hotter. The standard timing lever of the Simms instruments permits of variations in the timing of the ignition over a range of 30 degrees, which is sufficient to meet the requirements of motors of five-inch bore and less.

Contact Breaker Cam Ring.

Another feature of the Simms instruments is the cam ring, which is constructed of a high grade material, hardened and ground to seven ten-thousandths (.007) of an inch. While it would appear that such close limits are not essential, it should be borne in mind that the synchronization of the spark with multi-cylinder motors is dependent, with magneto ignition, upon the break of the primary current, which is made by the contact points. The last named are primarily actuated by the cam ring, which depresses the lever

Fig. 121—Simms SU48 Magneto, a True High-Tension Instrument Utilizing a Commutator Instead of the Usual Double Circuit Breaker Mechanism.

of this concern is standard equipment on both commercial and pleasure vehicles. While in the main the principles involved in the Simms instruments are similar to those types previously presented, there are several features which differ from conventional practise. The company attributes the efficiency and durability of its magnetos to these features and to the use of the highest grade of material by skilled workmen.

How Design Differs.

The features referred to consist of the Simms patented pole shoe and the specially constructed contact breaker ring. The former is shown at Fig. 124, and it will be noted that each pole shoe has a decided extension and that these projections are diametrically opposed. The quality of the construction emphasized by the maker is that the armature cuts the maximum lines of force at both fully retarded and advanced positions. It has been explained that the output of a magneto depends wholly on the number of lines of magnetic force which are cut by the armature in its rotation, and that it is desired to cut these lines at a point where the hottest spark may be obtained.

Generally, it is customary in starting the motor on the magneto to advance the spark lever so that the greatest number of lines of force will be cut, or, in other words, the contact breaker housing is rotated to bring about an earlier break, because the crankshaft

Fig. 122—Simms SUW6 Magneto, Having Water Proof Features and Being Compactly Designed.

carrying the movable platinum point, the operation of which has been fully explained. The Simms cam ring is shown at Fig. 125, which illustration also depicts the end cap and distributor housing or plate displaced.

Fig. 123—Simms Dual Contact Breaker and Brushes.

All Simms instruments are of the true high-tension type, having a double wound armature, the high-tension current resulting from the secondary winding and eliminating the need of a step-up or transformer coil. They are constructed to meet the requirements of different types of internal combustion engines, and letters and numbers are utilized to distinguish the different models, also in single (independent) and dual forms. The SU4 is of the independent design; is employed with four-cylinder motors, and the motor is started and operated on the instrument. The SU6 differs only in that it is constructed for six-cylinder engines. Both of these types are manufactured in the dual form, the four-cylinder instruments being designated by SU4S, and the six-cylinder magnetos by SU6S. Water proof magnetos are produced both in single and dual forms, for four and six-cylinder engines, and are identified by the markings; for example: The four-cylinder independent is marked SUW4 and the dual SUW4S; the six-cylinder independent SUW6 and the dual, SUW6S. The SU4S is shown at Fig. 121 and the SUW6 at Fig. 122. No sectional view of the instruments is shown, as the general construction is similar to those high-tension magnetos previously described.

Materials Employed.

The base and end plates are of heavy bronze, and all matched surfaces are machine finished. No white castings are utilized at any point where strength and

Fig. 124—Simms Pole Shoe, Having an Extension.

durability are essential. The armature is mounted on imported annular ball bearings, and the distributor bearing is a ground shaft running in a reamed bronze bearing, which is grooved for oil, lubrication being provided by a felt wick feed from an oil reservoir. The distributor board is

fitted with screw terminals, suitable for the Simms cable end, or the leads may be attached direct to the terminals, thumb screws being utilized to retain them.

The usual indicating window or "sight hole" is provided in the distributor board or housing, making timing of the instrument a simple matter. The distributor is dust and water proof; is retained by three screws, and the carbon brush, shown at Fig. 125, is of ample size. The brass distributor segments have a large surface, insuring maximum durability.

The timing lever has an arm on either side to facilitate its connection with the spark control mechanism. The lever is eliminated in the fixed spark instruments. The SU4 independent can be fitted with a stationary cam ring for fixed ignition. The platinum contact points are of the best of material, extra large in diameter, and are easily accessible for inspection and adjustment. The end cover or dust cap is retained by a spring lever and is quickly removed when desired. All important dimensions, such as diameter and taper of shaft, height of shaft from base and drilling of bolt holes in base for retaining the instrument, are in accordance with S. A. E. standard. The safety

Fig. 125—End Cover and Distributor Plate Removed from Simms Magneto to Show Circuit Breaker Mechanism and Distributor Brush, Segments, Etc.

spark gap is visible through a small window under the oil flap on the rear or driving end.

Circuit Breaker Mechanism.

The circuit breaker mechanism of the independent type of magneto is shown at Fig. 125. It follows conventional practise and is attached to and revolves with the armature shaft. That employed with the dual instruments differs, as also does the cover or housing. The difference between these members is shown by Figs. 121 and 122, the former being the dual magneto. It will be noted by referring to Fig. 123 that the circuit breaker mechanism is provided with two brush holders and that a heavy carbon brush is fitted to each. They are easily removed and replaced, although it is stated that they will require no attention.

Operation of Commutator.

The Simms dual types of magnetos, which permit of utilizing a storage battery or a certain number of dry cells as an independent source of current supply, such

as for starting or operating the motor, differs materially from conventional design, in that the dash switch contains no induction coil or high-tension switch. A vibrating or battery spark is, however, obtained through the use of a coil, and, as is generally the case with dual systems, one set of spark plugs serves for both the battery and magneto currents.

The Simms system differs from the dual forms of magnetos previously described in that the usual extra circuit breaker mechanism is eliminated. The maker lays great emphasis upon this point, calling attention to the simplicity of wiring and the small number of leads and connections. It has but three low-tension connections to the dash switch and but one to the battery. This is made clear in the wiring diagram shown at B in Fig. 130.

Fitting the Commutator.

The commutator is depicted at Fig. 127. It comprises a disc of special heat resisting, insulating material, into which are molded four bronze segments,

Fig. 126—Simms Two-Point Switch, Having but Two Positions—The Button Is Utilized for Starting on the Battery Sparks.

these being spaced equidistant. Two of these segments are connected with the terminals of the commutator, the other two simply serving as a path for the contact breaker brushes. The commutator is fitted to the timing lever, in place of the usual dust cover, and retained by a flat spring. It is located in its proper position by a pin projecting from the timing lever, which engages a corresponding keyway or slot in the commutator.

Simms Dual Switch.

The dual switch employed with the magneto is shown at Fig. 126. It is compact and simple and is provided with lock and key. The latter may be removed after throwing the lever to the "On" position, and there is but one other position, that of "Off". Its operation is simple. To obtain the battery and the magneto spark, the button marked "Battery" is pushed in and rotated slightly to the right. If the commutator brushes are on live (short) segments, a constant shower of sparks will be delivered to the cyl-

inder on compression, and if the latter be charged with a suitable mixture it will be exploded. This is generally termed starting on the spark from the seat.

Upon the motor starting the button is released and the magneto supplies the current for ignition. It will be seen that this obviates the moving of the switch lever from a "Battery" to a "Magneto" position, as is customary practise. It is held to be impossible to throw the switch

Fig. 127—Commutator of Simms Dual System.

lever to the "Off" position with the battery push button locked in position, a construction which prevents waste of the battery current should the operator be careless. One of the qualities of the Simms two-point switch is that when the lever is thrown to the "Off" position it locks automatically. From the above it will be seen that the switch is simple.

Components of Switch.

The dual coil is of the dash, cartridge, water proof type, as will be noted by reference to Fig. 126, the coil proper being located in service under the hood, the switch being placed on the driver's side. Its interior consists of a plain magnet wound with heavy wire, a condenser and an extra rapid vibrator. Instead of utilizing an induction or step-up coil for transforming the battery or low-tension current, the secondary winding on the armature shaft is employed. No sliding contacts are used and, as will be noted by referring to the wiring plan shown at B, Fig. 130, there are but three low-tension connections from the switch to the magneto and one to ground. One of the qualities of the design emphasized is that any error made in

Fig. 128—Cover of Simms Switch Displaced to Show Simplicity of the Design.

connecting the magneto to the switch will not injure the system and no harm, other than exhausting the battery, can occur if the switch is accidentally left

on the "On" position with the motor stopped.

Another quality of the system is that should the coil be damaged as in an accident, the motor can be

Fig. 129—Independent Magneto Switch.

operated on the magneto alone, as it is a true high-tension instrument. It is also pointed out that the dual coil will provide a vibrating spark for every position of the crank shaft from which the motor can start on the spark, and that the possibility of a back fire when starting with the lever retarded is limited to about 10 degrees on the compression stroke at dead centre.

The current consumption is said to be very low, approximately 1.75 amperes for starting and .75 when operating. It is also stated that the switch cannot be burned out with any six-volt battery, which is used. The maker emphasizes the claim that the vibrator will not require adjustment or attention only after long periods of service, owing to the large contact points utilized. Should adjustment be necessary it does not involve dismantling the construction, as a screw for this purpose is provided in the centre of the push button, as will be noted by reference to Figs. 127 and 128, being exterior and interior views respectively. The contact points are brought closer together by turning the screw, only a slight movement being necessary.

Adjusting Vibrator.

Should it be desired to displace the cover, it is accomplished by inserting a pin accompanying each system, and rotating the cover plate a quarter-turn. By slipping the spring locking ring out of position, the entire switch mechanism may be removed and without the use of tools. All switch bodies and parts are interchangeable, assuring easy replacement in the event of accident or repair.

The Simms Magneto Company states that the best results are obtained with a spark plug gap of one-fiftieth inch, and that platinum contact points should

be set to the gauge accompanying each magneto, rather than by attempting to utilize other measurement. One or two drops of fine oil in the two holes, which are plainly marked, about every 1000 miles of service is sufficient to lubricate all parts.

The armatures of the Simms magnetos are carefully wound and the wires are protected by an insulation of high dielectric strength, which is impervious to moisture. The entire winding is impregnated with an insulating compound, baked on, so that no section of the armature can absorb moisture.

The independent types of instruments are intended for motors up and including five-inch bore, and no batteries are employed for starting or operating. With motors difficult to crank the magneto may be employed with an independent battery, timer and coil system when the power plant is not equipped with a motor starter. The product of the Simms Magneto Company is guaranteed.

(To Be Continued.)

COOK GENERAL SALES MANAGER.

Otis R. Cook, who is one of the best known men in the selling organizations of motor vehicle tire manufacturing concerns, and who had for four years been connected with the Kelly-Springfield Tire Company of New York City, has been made general manager of the company and is located at the headquarters at Cleveland, O. Mr. Cook has been for 18 years connected with the industry and his knowledge of the industry and trade has been the result of long experience in differing capacities. He was in the service of the B. F. Goodrich Company, Akron, O., for 10 years, and resigned that connection in 1906 to become personal representative of H. S. Firestone, president of the Firestone Tire & Rubber Company, Akron, O. In 1908 he resigned to go to the Federal Rubber Manufacturing Company, Milwaukee, Wis., as general manager, and in 1910 went to the Kelly-Springfield Tire Company as manager of the Cleveland branch and personal representative of Van H. Cantwell, president of the company. His success in that capacity resulted in his latest appointment as general manager.

HINTS FOR PROPER MAINTENANCE.

CONSIDERABLE ingenuity is displayed by repairmen in overcoming various machining difficulties, and an instance of a useful lathe attachment

readily made to follow the required circular path, as shown.

GROOVING OIL DUCTS ON LATHE.

Cutting in oil grooves in bearings with a chisel is not a satisfactory method and considerable time is lost in the operation. The proper method is to utilize an oil grooving machine, but these are not common in repair shops. In an accompanying illustration is presented an attachment for an ordinary lathe which the repairman who constructed the device states can be utilized to groove any size bush or bearing. The drawing is practically self-explanatory, but the chief points to be considered are that the arrangement should be bolted firmly to the lathe body and that the adjustable arm connecting the carriage with the horizontal disc should be parallel with the lathe bed at each end of its stroke.

The screw in the carriage holder must be withdrawn before commencing operations, so as to enable the carriage to slide easily in either direction. The drive must be so proportioned as to enable the chuck to make one revolution while the tool is travelling the whole length of its stroke. An oil groove will thus be made to feed oil equally all over the bearing. For example: Assume a bush 1.5 inches long is to be grooved. The pin on the horizontal disc is set .625 inch out of centre; the connecting rod adjusted and the main carriage bed locked. The transverse screw is then removed from the tool carriage and the grooving tool set about .125 inch inside the bush, and the lathe started.

The carriage being free to slide, the connecting rod will cause the tool to travel just 1.25 inches, and

is described in a current issue of the Commercial Motor, an English publication. The repairman had occasion to replace parts of a badly damaged torque tube and ball universal joint, and, when he came to turn the ball and its seating, was confronted by a problem, inasmuch as the only machine available was a 12-inch centre lathe.

An accompanying sketch shows the attachment constructed and applied, and demonstrates how the concave and convex surfaces required were turned. The upper drawing shows the attachment for turning the concave surface; the lower depicts the ball being machined. The diagram underneath each lathe illustrates the path of the cutting tool, this being indicated at A and C.

The inventor of the attachment states that it was constructed without trouble. It consisted of flat mild steel strips, the sections being .5 inch by one inch. Six lengths were cut off to obtain the necessary travel, and at the base of the angle pieces were drilled two .375-inch diameter holes. The plain ends were drilled out .5 inch.

The swivelling connecting rods, two in number, were drilled out and tapped .5-inch Whitworth at each end, the centres being carefully marked out equal to the radius of the ball and spherical seating; that is, four inches. Permitting these to swing at the end of each angle piece enabled the necessary arc of the cutting tool to be effected.

It will be noted that for either machining operation, one angle strip is bolted to the loose headstock of the lathe, and another piece to the top slide under the tool rest. Cross feed only is used, the transverse feed being free altogether so that without touching the handwheel the carriage may readily be pushed along the lathe bed. The cutting tool may then be

Device for Machining Concave and Convex Surfaces on Centre Lathe: A, Path of Cutting Tool for Ball Seating; B, Swivelling Links for Procuring Radii; C, Path of Cutting Tool for Sphere.

Attachment for Grooving Bearings on Lathe: A, Grooved Brass in Section; B, Arrangement of Drive; C, the Work Piece; D, Disc Drilled to Give Various Strokes; E, Adjustable Connecting Rod; F, Screw, Which Is Removed to Allow for Free Travel.

the gearing being so arranged that the chuck will make one revolution during the complete travel of the tool, a groove of the required length and pitch is cut.

MACHINERY, TOOLS, EQUIPMENT AND SUPPLIES.

THE Green & Swett Company, 737 Boylston street, Boston, is manufacturing the Tri-Phoon garage pump, which is not only moderately priced, but is very small and compact, occupying but little room in the garage. One of the qualities of the pump is that it does not require the use of a pressure tank, as tires can be inflated directly and very quickly. The cost of operating is slight.

The pump is made in three and six-cylinder forms and the motor employed for the smaller size is constructed for either a direct or alternating current. The six-cylinder unit is also marketed for either direct or alternating current.

One of the features of the Tri-Phoon is that it may be driven at a high rate of speed without injury to the working parts. As shown by the accompanying illustration, it includes a .25 horsepower electric motor, suitable length of flexible cord with plug, hose, pressure

Tri-Phoon Electrically Driven Garage Pump.

gauge and switch. The equipment is mounted on a substantial platform truck, which has a convenient handle for moving it about the garage. The Tri-Phoon garage pumps are adapted for both private and public garages, and the guarantee is very liberal, the maker offering to replace free of charge any pump found to be defective or faulty in construction within a year. Descriptive matter will be supplied upon request.

HOYT FORD MAGNETOMETER.

The Hoyt Electrical Instrument Works, Penacook, N. H., maker of fine electrical indicating devices, has brought out a new magnetometer for the model T Ford which presents many practical features and is moderately priced. The Hoyt differs from other instruments utilized to ascertain the condition of the Ford flywheel magneto in that it is connected permanently in the circuit, being mounted on the dash. It is a sturdy little instrument, and is but two inches in diameter.

As will be noted by the accompanying illustration, the dial is calibrated, the letters indicating Poor, Medium, Good and Excellent. With the magneto operating, the indicating hand moves over the dial, indi-

cating the condition of the generator at various speeds. The efficiency of the magneto is determined easily. After installing the magnetometer, readings at various speeds are taken, and by comparing these with those taken later, it is a simple matter to learn if the efficiency of the magneto is not up to standard.

The Hoyt instrument is easily attached by drilling two .1875-inch holes in the dash and securing the studs by lock washers and nuts.

The wiring is simple and the entire construction can be installed in a few minutes. The Hoyt is constructed with the same care and high grade material for which the product of this concern is noted. Each instrument is carefully tested.

Hoyt Ford Magnetometer.

PUMPLOK.

The Charles H. Simerson Company, 4135 Hudson boulevard, West Hoboken, N. J., has been organized to manufacture the Pumplok, which is held to solve waste in handling fuel and to possess other practical features. One of the qualities of the device is that it is stated it may be attached to a standard pump in 10 minutes by engaging the main shaft by means of a slotted shaft, the construction being retained in place by an adjustable clamp that is locked and sealed, as shown in an accompanying illustration. It not only prevents unauthorized drawing of gasoline, but checks the amount drawn by each person having access to the pump.

The drawing of fuel is made possible by the use of key checks, each person being supplied with a given number bearing his number or individual design. Consequently, each must account for as much gasoline as represented by the checks found in the Pumplok's receptacle. A simple tally sheet is utilized and the operator sets down the quantity drawn, and the price for cash or charge sales.

A separate counter is incorporated, showing tenths of a gallon, which may be adapted to single or double acting pumps and to indicate the actual amount of gasoline drawn, whether in even gallons or fractions. A separate key check is required for each gallon or fraction thereof, and the pump is locked at the comple-

Simerson Pumplok.

tion of each drawing, so that the next operator cannot take advantage of the fact that only a fractional quantity was drawn by the previous workman. The amount drawn is set down on the tally sheet as shown by the counter.

O. K. TOOL POST.

The O. K. Toolholder Company, Shelton, Conn., of which C. Hilterbrant, 99 Nassau street, New York

O. K. Tool Post for Holding Tool on the Side and for Adjusting It Vertically.

City, is direct representative, is manufacturing the O. K. tool post holder, shown in an accompanying illustration. It holds the tool on the side, thus enabling one to get up near the chuck or face plate. With this tool post the tool is adjusted vertically, thus maintaining the clearance on the cutting tool. The tool post swings around at any angle.

It is stated by the company that after placing it in the desired position, the process of tightening has no tendency to twist the tool post, and that the bolt is made to fit the T slot so that there is no danger of injuring the same. The nut is made to fit the tail stock wrench.

When it is necessary to grind the tool and it is desired to remove the tool or holder, the vertical adjustment is not affected. By swinging the tool post around at right angles and using a small V block, it is held that the design makes the strongest kind of a boring tool holder. All parts are steel drop forgings, carefully machined, case hardened and interchangeable. The O. K. comes in three sizes, the No. 1 post being suitable for 14 to 18-inch lathes, the No. 2 for 20 to 28, and the No. 3 for 30 to 40. The tool post No. 1 is adapted for holders from one inch to 1.5 high and any width, the No. 2 from 1.25 to 1.75 high, and the No. 3 from two to 2.5 inches high and any width.

The O. K. Tool Holder Company also manufactures the O. K. system of tool holders, and tools for lathes, planers, shapers, boring mills, etc.

K & B ADJUSTABLE WRENCH.

The Kilborn & Bishop Company, New Haven, Conn., is manufacturing the K & B adjustable wrench,

which opens on an angle of 22.5 degrees with the handle, permitting of its use in places difficult of access with ordinary tools. All parts are interchangeable and carefully fitted. The movable jaw and handle are each a solid piece steel drop forging. The shape of the handle is such that the hand readily becomes conformed to it.

HERZ AUTOMATIC TIMER.

Herz & Co., electrical engineer, is marketing the Herz patented automatic time adjustment for ignition apparatus. It is designed not only to prevent accident through back firing, caused by improper advance of the spark, but it is held to make for economy in the operation of pleasure and commercial vehicles. The time of ignition is adjusted automatically in accordance with the number of revolutions, and the range is up to 40 degrees.

The components of the device are shown in an accompanying illustration and it will be noted that it comprises a coupling consisting of two juxtaposed discs, the construction being interposed between the magneto and driving shaft. Each disc is provided with five grooved curves running in an opposite direction to those in the other disc. Five steel balls are held in these grooves and function in a similar manner to the weights of a governor, being forced outward by centrifugal force in direct proportion to the speed of the motor. The maker states that this construction imparts a twist to the armature of the magneto in relation to the driving shaft.

It is held that any desired degree of adjustment may be obtained by altering the curves in a suitable manner, and that the absence of springs, journals, joints, etc., and the certainty with which the balls are guided, make for reliability of operation.

The device is supplied either as an integral part of the ignition apparatus or in the form of a coupling. Owing to the small space it occupies it is stated that in many instances it can be used in place of the ordinary coupling and without alteration. All parts are made to gauge, are interchangeable, and constructed of the best of material. Special literature is issued by the company and will be sent free on request.

Herz Automatic Time Adjustment for Ignition Apparatus Up to 40 Degrees.

CORRESPONDENCE WITH THE READER.

Lubricating the Motor.

Will you explain in a non-technical manner the various oiling systems utilized with gasoline motors? After visiting the Boston show and in reading over the catalogues I collected, I found the terms used about the oiling systems confusing.

W. J. D.

Boston, March 22.

Lubricating systems may be divided into two general classes, splash and pressure, and these combined.

Fig. 1—Showing Leads Utilized in Pressure or Constant Circulating Type of Lubricating System.

The principle of the splash system is one in which the ends of the connecting rods dip into an oil reservoir in the lower half of the crankcase, splashing the lubricant to the working parts of the motor. The system may include means for feeding the lubricant to the crankcase, such as a pump, or by utilizing the pressure of the exhaust to force the oil to the reservoir, etc. Provision may also be made to maintain a certain level of oil in the crankcase, and when such is the case the system is termed the constant level splash.

The pressure or constant circulating principle involves the delivery of the lubricant from the reservoir through piping to the main bearings, connecting rods, etc., from which the excess oil gravitates back to the reservoir, where it is again taken up by the pump and again circulated. The splash-pressure system is a combination of the two above described. There also is the non-circulating system in which the oil is used but once.

An example of the pressure or constant type is shown at Fig. 1, the illustration depicting a system utilized in the motor of a pleasure vehicle, to bring out the points described. It will be noted that the crankshaft and camshaft are drilled from end to end, and that there is an independent feed of oil direct from the pump to the seven main bearings of the crankshaft and to the ends of the camshaft. There are outlets for each of the five bearings of the camshaft, similar to those through which the oil reaches the crankpins from the hollow shaft. From the chief distributing points at the main bearings the lubricant is conducted through the hollow crankshaft to the crankpins and from them to the wristpins, so that the oil is delivered under direct pressure to the parts. A gauge on the dash indicates the pressure under which the system is operating. The path of the lubricant is

easily followed in the illustration by the black lines.

A combined system, which is catalogued by the maker of the car as automatic, is shown at Fig. 2, it being employed with a well known machine. It provides the splash feature, as the lubricant is delivered to a trough under each connecting rod, the oil being forced to the vessel by a pump. These troughs tilt, being connected to the throttle in such manner that at high motor speeds the ends of the connecting rods dip deeper. The oil levels at varying speeds are indicated by dotted lines. The linkage and oil reservoir are also shown.

Governors.

Are governors practical for a truck? Will they prevent overspeeding? How is it accomplished? PRACTICAL.
Waterbury, Conn., March 19.

The use of governors on motor vehicles is not new, as they were formerly fitted to pleasure cars. When employed with a commercial vehicle their function is to prevent the car exceeding a predetermined speed, and generally the device is fitted to the carburetor. When so used it controls the amount of mixture passing to the cylinders, a form of valve being employed which automatically opens and closes, its action being regulated by the speed of the motor.

Centrifugal governors are also utilized, these generally being operated by balls or weights linked to one of the revolving spindles of the motor, and also linked to a collar or sleeve sliding on the same spindle. The weights are normally held close to the spindle by springs, but as the speed of rotation increases the weights fly outward, more or less, and in so doing move the collar lengthwise. The collar is generally connected to the throttle, so that when a certain speed is attained the governor begins to cut down the supply of mixture. This slows the motor, the weights return inward, the collar moves back and the throttle is again opened so that the motor picks up its speed once more.

Some governors are adapted to act on the valve mechanism so as to modify the operation of the

Fig. 2—Combined Splash and Pressure Feed Lubricating System—It Is Also Termed Automatic Because of the Use of Tilting Troughs.

valves, varying the lift of the inlet or exhaust members. A description of a governor for commercial vehicles will be found elsewhere in this issue.

GOODYEAR SELLING POLICY.

The statement is made that the Goodyear Tire & Rubber Company has established a policy that will be applied eventually throughout the country as rapidly as this can be accomplished, this being to manufacture and supply tires from branches or service stations direct to the retailers, this meaning the eventual elimination of all retail selling. The reasons for this are that in the maintenance of its own retail departments the company is actively competing with the retailers, who believe they are entitled to all the business they can develop, and the company has been very considerate in its relations with retailers, crediting them with business that might possibly be regarded as its own. The maintenance of the retail stores has been expensive as well, and the wholesale distribution can be made for comparatively reduced cost. For these reasons the sales departments will be combined with the service stations in the larger cities and the retail trade will be handled by the dealers and agents, who will be given all necessary assistance and support from the factory sales organization. The withdrawal of the retail competition will also be an incentive for the retail dealers to carry larger stocks, to meet every probable demand upon them.

A KisselKar truck in the service of the Marshalltown Bottling Works, Marshalltown, Ia., which has been used since July, 1912, is credited by General Manager F. G. Bailey as having saved half its cost, for it has replaced seven horses and the work is done better than it could be with animals. The machine is used in very hard cross country haulage.

The Gramm-Bernstein Company, Lima, O., builder of B. A. Gramm's trucks, paid a semi-annual dividend of 3.5 per cent. on its preferred stock April 1. The company's report shows a gratifying increase in number of trucks sold and the indications are there will be a substantial growth of business during the coming year.

Howard Limrick, who was manager of the Boston branch of the B. F. Goodrich Company for 12 years, has resigned that position to become manager of the Boston branch of the Kelly-Springfield Tire Company. William Moore succeeded Mr. Limrick as manager of the Goodrich branch.

The Mercury Manufacturing Company, Chicago, Ill., makes but one type of vehicle, a 1000-pound wagon, that it has produced for four years, and is in no manner connected with the manufacture of the Mercury cyclecar.

J. E. Morgan, formerly with the Metzger Motor Car Company, has been made assistant sales manager of the Standard Motor Truck Company, Detroit, Mich.

VANDERVELD GEAR SHIFTER.**Mechanical Selection of a Gear Ratio by Button and Change by Pedal.**

The Vanderveld gear shifter, the invention of A. Vanderveld, and manufactured by the Grand Rapids Show Case Company, Grand Rapids, Mich., is a foot-operated, mechanical gear shifting device that may be applied to any form of motor vehicle, either passenger car or service wagon or truck, the selection being made by pressing a button. The shifter as used weighs about 10 pounds and it is mounted convenient to the transmission gearset to have easy means of linkage and operation. Placed on top of the steering wheel, or near to it, are the buttons, one for each speed ratio or gear. Attached to the clutch pedal is a lever or arm that has mounted on it two blocks adapted to engage the gearshift fingers, there being one for each of the gears, which is connected directly to the rods that are coupled to the push buttons.

The Vanderveld Mechanical Gear Shifting Device as Installed in a Pleasure Car Chassis.

Pressing any button raises the finger connected with it into the path of travel of the shifting blocks, and the forward movement of the clutch pedal through the block contacting with the finger pulls the gear into mesh. If at the time a gear is in mesh, as the clutch pedal is pushed forward the block first contacts with a neutralizing member which releases the gear in mesh, and when the gear is made neutral by further movement of the clutch pedal the block contacts with the finger, which selects a block and pulls it through.

The pressing of the button does not actually shift the gears, this being done by the forward movement of the pedal, so that one may at any time select the next speed one expects to use, or this predetermined choice may be changed by pressing the first selected button and the next complete forward movement of the clutch pedal actually affords the speed ratio selected. A material gain in gear changing is made by this method of predetermination. No springs are used in the shifting of gears, the entire operation being a positive mechanical action, conventional clutch pedal. Being positive in action and allowing the "feeling in" of the

gear, the driver's hands are free for steering, the device facilitates operation in traffic and on rough roads, and eliminates the shifting lever and insures greater accessibility to and from the machines. When applied to trucks, gearset wear is minimized and danger of stripping gears is eliminated. The illustration shows the device installed in a passenger machine.

SOUTHER ELECTED VICE PRESIDENT.

Henry Souther, one of the best known consulting engineers of the motor vehicle industry, who for four years had been associated with the Standard Roller Bearing Company, Philadelphia, Penn., in that capacity, has assumed the duties of vice president of the Ferro Machine & Foundry Company, Cleveland, O., to which position he was recently elected. Mr. Souther is recognized as an authority on metallurgy. He is a graduate of the Massachusetts Institute of Technology, and his early work was with the Pennsylvania

Henry Souther, Vice President, Ferro Machine & Foundry Company.

Steel Company, leaving that concern in 1893 to become an engineer for the Pope Manufacturing Company at Hartford, Conn. He resigned this position in 1899 and established a laboratory at Hartford, and his services were much in demand by motor vehicle manufacturers. He was consulting engineer for the Association of Licensed Automobile Manufacturers and has been prominent as a member of the Society of Automobile Engineers, serving that organization as president in 1911.

The Mason-Seaman Transportation Company, with capital of \$10,000,000, has been incorporated in New York City by Will B. Harding, James M. Shaw and P. Francis Alther, to engage in a general cab, livery and automobile business.

The plant of the Sandusky Auto Parts & Motor Truck Company, Sandusky, O., is to be used for building tractor engines by a company of which George W. Schwer, vice president of the Ohio Motor Company, is organizer.

The Aluminum Castings Company, Cleveland, O., has located the offices of its general manager and purchasing agent at Detroit, Mich.

LOCAL TAXATION POSSIBLE.

If the bills now pending before the New York legislature become law, the provisions of the Callan law, which now is in force, which provide for state taxation through the payment of registration fees, will be repealed, and instead a flat rate of \$2 for registration will be established, and the vehicles will be taxed at the local rates in the communities in which they are owned. This is based on the demand among the legislators for the distribution of the tax upon the machines in the villages, towns or cities in which they are owned, that these communities may distinctly benefit, instead of the state. The bill that repeals the Callan law provides that no person shall drive a motor vehicle who is intoxicated, and for the violation of the statute there are penalties that may be fines up to \$500 or imprisonment for a year, or both, at the discretion of the court. The other bill is a general amendment of the law relating to the use of the highways by all vehicles.

TO SELL ATLANTIC VEHICLE COMPANY.

George W. C. McCarter, trustee in bankruptcy for the Atlantic Vehicle Company, has invited bids for the sale of the plant and equipment of the company at 357 Oraton street, Newark, N. J., consisting of the office furniture and fixtures, material, uncompleted and completed motor trucks, the drawings, blue prints and the good will of the business. Sealed bids will be received by the trustee at his office at the Prudential building, Newark, to April 14, and the bids will be opened the following day at the office of Edwin G. Adams, referee in bankruptcy, Essex building, Newark. If the bids are not accepted the property may be disposed of at public auction.

The Hackney Manufacturing Company, St. Paul, Minn., has been acquired by the Standard Motor Company, Mason City, Ia., and the members of the Hackney company have been added to the board of directors of the Standard Motor Company. The manufacture of Hackney automobile plow tractors will be continued at St. Paul.

The American Electric Car Company has been incorporated at Portland, Me., with capital of \$1,500,000, to manufacture and deal in automobiles and parts, etc., by F. A. Brand of Cleveland, O., and T. Huss of Saginaw, Mich. This is the company formed by the merging of the Argo, Borland-Grannis and Broc companies.

Plans are now being prepared by Safety Director Holmes of Cincinnati, O., for the complete motorization of the fire department of that city, and an appropriation of approximately \$250,000 will be asked to accomplish this result.

FEATURES OF 1914 POWER WAGON DESIGN.

Characteristics of Machines That, Seemingly Incidental, Are of Material Importance in Increasing Efficiency and Reducing Expense of Operation.

THE statement that motor vehicle practise has converted engineering theory to a material extent may be surprising to those who regard science as applied to construction as infallible, but in the evolution of power driven vehicles, from the carriage designed for animals, converted by the installation of an engine, to the seemingly perfected automobile of latest type, many principles were established that were at variance with those accepted by engineers as being sufficient. Few of the concerns organized at the inception of the industry were founded to build service wagons and trucks. Automobiles were regarded as suited for pleasure purposes only and not practical for freight transportation. For the reason that there was really no demand for either wagons or trucks, those who engaged in constructing them found no encouragement, and production, generally experimental, was

vehicles learned from experience that the constructional requirements were entirely different with the two types of machines. Principles that could be applied to other constructions failed because of the stresses that had not been anticipated, and material that for many purposes was in every way sufficient was found inadequate from the deterioration from vibration.

Fatigue Caused by Vibration.

Crystallization of metal, which is otherwise known as fatigue, is the greatest enemy of motor vehicle engineers. This condition is certain to result, no matter how carefully a design is created, and the hope of practically every designer is to defer it by providing differing forms of protection. There is no question that the high grade metals will endure longer than the cheaper, and yet there is no definite gradation of

Some Examples of Spring Design: The Linkage of the Shackles of the Pierce-Arrow Two-Ton Chassis, the Pivoted Ends of the Rear Suspension of the Chase and Atterbury Worm Driven Machine, the Rear Connection of the Walter Front Spring and the Hanger of the Rear Spring of the Same Truck.

not only costly, but disappointing to those who sought to utilize these machines.

The majority of the older concerns building power wagons today originally manufactured pleasure vehicles, and with a foundation of engineering knowledge based on experience with these types of vehicles the freight machines were developed. In some instances the designs were worked out with extreme care, expense was not spared in experimental development, and no vehicle was offered for sale until it was believed to be equal to the requirements. These machines have been comparatively little changed as a rule. In other instances pleasure car design was adopted with a result that efficiency and endurance were lacking, and reputation was sacrificed.

The scientific combination of metals, for demand for material of extreme strength stimulated the production of alloys, insured construction of light weight for pleasure cars, but the engineers designing freight

the service value of metals because of the wide diversity of uses and conditions of operation, all of which have potent influence. Scientific production of material, careful determination of physical elements before use, and special treatment, will insure exact quality, and proportioning will afford a sufficient factor of safety, but obviously this is as far as engineering skill can go, for use in every case will differ, and this cannot be anticipated.

Because of the vibratory influence upon the metal of a chassis the springs that support the frame are of the greatest importance. The wheel is supported by a rubber tire that is distorted by pressure upon it and there is some degree of resiliency afforded by it, this lessening as the tire wears. The wheel and the axle and the springs are assembled solidly in contact with each other, so that the road shock, which varies with the weight, speed, character of obstruction and the condition of the tire, is communicated through the

The Cored Cast Steel Forward Hanger of the KisselKar Rear Springs; the Rectangular Bracket and Shackle of the Front End of the Kelly Five-Ton Truck Rear Suspension, and the Forward Shackle of the Rear Spring of the Four-Ton Packard Chassis.

wheel and axle, and is supposedly absorbed by the spring. The tire deadens the shock, but the vibration of the wheels, axles, springs and other connections is material.

Stress Absorption by the Springs.

The frame and the mechanism it supports is, however, subjected to the vibratory influences of the motor, which is operated at greatly varied speeds, and these are also assumedly absorbed by the springs. Thus it will be seen that the springs perform a double function so far as protecting the construction is concerned, to say nothing of the protection of the freight. Theoretically the springs ought to be as resilient as possible. This resiliency is secured by tempering, but the other metal components are heat treated to obtain toughness. The frames of most motor vehicles are suspended on shackles that are carried on brackets or hangers at the rear end, and on front springs that are pivoted transversely at the spring horns and fitted with shackles at the rear ends. This construction permits unrestricted deflection and reflexion of the rear springs, the drive being taken by radius or torque rods or tubes, and the fullest action of the springs is obtained. The forward springs are so mounted that the vertical movement of the axle is not limited, but the wheels are drawn by the forward section of the

springs. The varying length from deflection and reflexion is provided for by the rear shackle.

The stress upon the front springs is entirely different from that endured by those at the rear. The forward wheels are free rolling and are carried by the momentum or velocity of the vehicle, and there are no traction or braking influences upon them. The springs carry but a small part of the load, and while they are expected to absorb a considerable part of the vibration of the engine, they are generally much lighter and more resilient than the rear suspension members. But these springs are usually shorter and lighter than the rear suspension, and with rare exceptions they are under the chassis frame, this manner of installation being necessary to permit the turning of the wheels.

Varying Effects Upon Springs.

The forward springs carry from 10 to 40 per cent. of the load, and the rear springs from 60 to 90 per cent., and with springs under the chassis frame there is more or less sideways that causes transverse stresses, these being in ratio to the weight and height of the centre of gravity of the freight carried. The experience with light vehicles is that the forward springs are usually sufficiently resilient in all conditions, but the rear springs are stiff and do not absorb the shocks as readily as when loaded, and with the

The Manner of Seating the Underslung Rear Spring of the Walter Five-Ton Front Wheel Driven Truck and the Large Bracket Housing the Forward Rear Spring Eye, the Arm Carrying the Full Elliptic Spring of the Buick Wagon, and the Rear Spring Seat and Double-Yoke Shackle of the Chase Three-Ton Truck.

heavier machines this effect is pronounced. Many designers have sought to minimize this result by varying the length of the springs, to obtain longer and easier movement, and by installing supplemental or auxiliary springs that will become operative after the main springs have settled to a certain point. Auxiliary springs, however, have no effect whatever unless the machines are carrying at least partial loads.

The springs are secured to seats on the axles, these being generally of somewhat larger area than the width of rectangular forms, and are usually special fittings with the housings that carry the live or floating types. Frequently saddles are used that are fitted above or under the springs, and the attachment is by clips or U shaped clamps that encircle the springs and saddles and are bolted to the axles or seats, or through yokes that extend across the ends of the clips. Being secured in this manner the resiliency of the springs is afforded by the sections extending from the seats to the shackles, and these vary from 18 inches with the light delivery wagons to 28 inches with the heaviest trucks, although with the largest sizes of underslung springs the section may be as

ally bushed with phosphor bronze, and the spring and shackle bolts are made large and are hardened, so that with the anti-friction quality of the bronze when contacting with the alloy or nickel steel bolts much longer service can be obtained. The bronze bushings or the bolts can be renewed as frequently as desired. Conventional practise is to fit the bolts with grease cups to insure constant lubrication, and this means largely increased endurance.

Adoption of Foreign Practise.

The designing of spring hangers or brackets is decidedly important in that these must be sufficiently strong to resist all strain, the stresses must be so distributed that the frame will not be twisted by side-sway, braking or traction torque, and action must at all times be free. The American practise has been to have the ends of the rear springs so coupled that there will be unrestricted movement, the driving thrust being taken by radius rods, while torque arms have been generally used to resist the braking and traction stresses.

The new Chase three-ton truck and the Atterbury 3000-pound wagon chassis have been designed in ac-

The Three-Point Suspension of the Parcel Post Kar: The Full Elliptic Spring Mounted Transversely on the Rear Axle, the Forward Spring Seat and Yoke for the Spring Clips, the Rear Shackle of the Front Spring, and the Forward Flat Spring from Which the Front End of the Frame Is Underslung.

much as 30 inches, because of the greater arc, measured from the centre of the axle seat.

Maximum Action at the Eyes.

But as the springs are composed of from five to 17 leaves, the greatest number at the centre, these gradually increasing in length, the greatest deflection and reflexion is at the ends, and no matter what the form of suspension the movement is maximum at the eyes. In the front springs the forward ends are pivoted transversely, but the motion there is not as great as at the rear ends, and the wear at the spring eye, on the spring bolt and on the bolt carrying the shackle, is decidedly increased.

The movement of the rear spring is much greater and the wear at the eyes is correspondingly increased from the deflection and reflexion, the traction and braking torque, contacting with road obstructions and the effect of sidesway, so that the effect is much more rapid. The springs must necessarily be tempered and for this reason the bolts will wear quickly. To prevent wearing the spring eyes are very gener-

cordance with French practise, which is to dispense with radius rods and to use comparatively flat arc rear springs which are pivoted transversely in the forward hangers, as are the front springs in American construction, with the rear ends shackled, all stresses being taken by the forward sections. Both of these machines are worm shaft and gear driven, and provision is made with telescoping shaft connections to prevent end thrust, for the rear axles will be moved backward and forward slightly with the deflection and reflexion of the springs.

The comparatively flat arcs of the springs (the Chase spring is straighter than the Atterbury) minimizes this movement, but there is greater wear at the rear spring eyes. The stresses upon the springs require larger and heavier hangers or brackets, and the Chase hanger is webbed and fitted so that it bears the full width of the frame, and the bearing surfaces are very large.

The master and main leaves of the spring are turned to form an eye, the two being an inch thick,

The Long Skeleton Type of I Section Torque Arm of the One-Ton Véhe Chassis, the Centre Frame Member of the Pierce-Arrow Two-Ton Chassis That Supports a Self-Aligning Bearing and the Main Driving Shaft, and the Sectional Rear Axle of the Atterbury 3000-Pound Machine.

and the other leaves are thin and longer than the average, being lipped to prevent separation. The spring bolts are very large and have bearings in bronze bushings. It will be noted from the accompanying sketch of the front end of the rear suspension that the spring is nearly flat when the vehicle is light, and when loaded it is practically horizontal, so that the driving thrust is almost parallel with the line of the chassis frame. The elimination of the radius rod is a decided saving in weight, and simplifies the construction and minimizes the wearing parts.

The second sketch shows the manner of retaining the underslung spring to the square section of the cast steel axle housing, by long clips that pass through the housing and a saddle on which is seated a large rubber check. The spring seat is formed with lugs that fit at either side of the axle and prevent longitudinal movement of the spring. The rear shackle is a double yoke with comparatively long arms that carry very large bolts, this providing for considerable movement of the spring with practically no resistance.

The Atterbury design has a bracket bolted to the frame side member with a curved arm extending in which is an eye. The arm is carried by a boss in the centre of the bracket, and this boss is bored in the centre to coincide with the eye in the arms. The spring eye is fitted with a bronze bushing and the spring bolt is carried through the arm and screwed into the boss, this giving a very light, but strong construction, retaining the spring rigidly, and bringing the chassis frame very low. This bracket takes all stresses, and, as may be assumed, the spring bolt is very large. The spring has a greater arc than the Chase, but this is materially reduced, however, when a load is carried.

Drive Through Front Springs.

The Walter front-wheel driven truck has the Latil spring suspension, this having the forward ends shackled and the rear ends pivoted in hangers, so that in this design the machine is really drawn by the springs. To secure sufficient turning radius for the wheels, however, the springs are mounted under the frame, and as there is not the driving thrust to be endured the principal purpose is to obtain a construction that will not yield under the drawing or pulling

strains. This form has been used in France for nine years with very satisfying results. The springs are carried forward on conventional shackles and there is a very free movement. The centres of the forward springs are bonded by sleeves shrunk on while hot, this insuring the retention of the plates without weakening them by drilling for bolts, and making a solid assembly that can be secured to the axle with certainty that it will not be affected by the strains upon the clips. No matter what the strain the spring leaves cannot be separated. The deflection caused by the driving torque is especially noticeable in this machine.

The underslung rear springs of this chassis are mounted at both ends in shackles, the front hanger being a cored casting that is bolted to the side of the frame, into which is fitted a heavy bolt carrying the usual yoke. But the rear shackles are yokes that are mounted on the arms of brackets bolted to the chassis frame side members, the ends being carried by bolts fitted through the spring eyes. The rear springs are secured to the axles by very heavy clips that encircle the springs, the ends being passed through and attached by nuts to square saddle plates on top of the axles. The form of the plate, with the diagonal webbing, is shown in the accompanying sketch.

The Pierce-Arrow Design.

The front rear spring hanger of the Pierce-Arrow two-ton machine is a large casting that is lightened by judicious webbing, and this carries at the lower end a long bearing in which is mounted the emergency brake shaft. The shaft carries arms at either end that are connected with the yoke ends of the pull rods of the brake linkage. The shaft somewhat stiffens the frame and preserves the relation of the frame members and springs. The rear ends of the springs are rigidly connected by a rod. The forward rear spring shackle is linked and this affords very easy movement when the spring is subjected to pressure.

The Buick delivery wagons are equipped with full elliptic springs at the rear, and the frame is strengthened by a cross member directly above the axle and in line with the centre of the upper halves of the springs. At either side a bracket is bolted that extends diagonally upward and ends in a wide seat to

which the upper half of the spring is bolted by clips.

The five-ton Kelly chassis is fitted with a forward rear spring bracket that is decidedly out of the ordinary. This is a casting that is bolted to the under web of the frame members, and instead of the usual arm there is a rectangular section with a web filling a considerable portion of the space within the rectangle. The spring shackle is rectangular, one section of which is fitted into the opening of the hanger and secured by a large bolt that passes through both sides. The spring eye is fitted into the opening of the shackle and mounted on a bolt. This form of shackle affords very wide bearing on the bolts and obviates all wear from side pressure that might result from the use of the ordinary form of shackle links.

Examples of Heavy Construction.

The four-ton Packard chassis has the rear springs under the frame, and the forward ends are mounted in shackles with flat side links, but to bring the spring close to the frame and afford ample bearing the bracket is placed in the channel of the frame member. The bracket bearing is the full width of the spring, being supported by webs. The links are large and the bolts extremely heavy. This design eliminates weight and insures abundant strength, as well as reduces the height of the chassis frame.

The three-ton KisselKar truck frame is mounted above the rear springs, and the forward shackles are carried on hangers that are cored to secure lightness, the size of the hangers as seen from the side of the chassis giving the impression of massiveness and unusual weight.

Body Carried on Three Points.

The suspension of the Parcel Post Kar is decidedly out of ordinary practise in that the frame of the machine is literally carried on three points. The frame is tubular and the forward end is underslung, being mounted on two long and nearly flat semi-elliptic springs, the body being supported on two brackets close to the front axle. The rear end of the frame is carried on a full elliptic spring secured to a bracket at the rear of the back axle, and so arranged that by removing a single pin the spring can be removed from

the axle. The side frame members terminate in curved arms or horns that are turned upward, and the upper ends are connected with a steel rod, this forming the forward member. The forward spring ends are pivoted transversely, but the rear ends are shackled to brackets mounted on the frame, the slow motion of the long springs being largely taken up by the shackles, which are of the side link type. The front springs are installed on seats that are fitted around the axle, the ends forming the yokes for the spring clips, and separating them sufficiently to give a large seating area.

The Velie one-ton delivery wagon chassis is shaft driven and the rear springs are shackled at either end. The driving and braking torque is taken by a long torque arm at the left side of the driving shaft that is pivoted on the axle housing and spring supported at the forward end. This arm is I section, with the web of the rear end cut to reduce weight.

Some Recent Adaptations.

The driving shaft of the Pierce-Arrow two-ton chassis is supported in the centre of the frame by a cross member that is slightly dropped, and on which is mounted a self-aligning bearing of large size. Just forward of this is a universal joint that is completely housed to protect it against dust and abrasive substances. This construction insures that the shaft will be relieved of all side pressure and end thrust, no matter what the distortion of the chassis may be.

The rear axle of the 3000-pound Atterbury worm and gear driven chassis is somewhat out of the ordinary in that the spring seats are of unusual length to insure against stresses from the drive through the springs, and the steel axle housing is formed of a centre and two end sections bolted together. On the centre section is bolted the mounting of the worm shaft. The end sections of the axle housing carry the brake shaft brackets, which are cast integral and machined, instead of being separate fittings. The axle is trussed to insure maximum strength.

One of the features of the Pierce-Arrow two-ton chassis is the manner of equalizing the emergency brake pressure, which is done through linkage that

Practical Methods of Brake Linkage: The Equalizer of the Pierce-Arrow Two-Ton Chassis, the Simple Equalizing Device for the Double-Acting Rear Brake of the Walter Truck, and the Shaft and Sleeve Form of Brake Rod Connection of the Kelly Five-Ton Trucks.

is actuated by a direct forward pull, through a yoke that is linked to arms clamped to a divided shaft that is mounted in extensions of the brackets carrying the spring shackles. These brackets are connected by a tubular cross member that ties the frame and supports the forward end of the torque arm. This hanger also supports the forward ends of the radius rods. The assembly is illustrated by an accompanying sketch.

One of the simplest of equalizing devices is that used on the Walter front driven truck, there being a rod extending back in the centre of the chassis frame. This is connected with the service brake pedal, so that pressure applied to the pedal will actuate the transmission brake as well as the rear wheel brake, the effect being on all four wheels. The rod has a turn-buckle section and a yoke end that is pivoted on a cross bar that is slidable in guides beneath the frame side members. The ends of the cross bar are drilled for the bolts of yokes that are in turn yoked with the adjustable ends of the brake pull rods. Thus every possibility of pressure preventing the effective operation of the brake is obviated. The pull rod is also so connected with the emergency brake lever that movement of this increases the pressure upon the brake shoes in the rear wheel drums, but does not affect the service brake.

The brakes of the Kelly trucks are internal expanding in the rear wheel drums, and these are operated by pull rods at either side of the chassis, within the frame. The brake shafts extend across the frame, consisting of a solid shaft and sleeve, the sleeve carrying a yoke that clears the pull rod, the longest arm forming the lever, and the shaft carries a similar lever arm. Both arms are connected by pull rods with lever arms mounted on short shafts and sleeves at either side of the rear axle.

(To Be Continued.)

FROM THE RAILROAD'S ASPECT.

Fred A. Hortter of Boston, car accountant of the Boston & Maine railroad system, who has given his subject careful study and can speak with experience and knowledge from the viewpoint of the railroad corporation, will deliver a paper on "The Effect of Power Wagon Operation on Terminal Freight Congestion" before the Electric Vehicle Association of America at the headquarters at 29 West 39th street, New York City, the evening of April 24.

Mr. Hortter's observation covers a long period of time and the paper will be of much practical value, for it will deal with the aspect of the railroads and will present conditions as generally realized by transportation companies. From this point of view the estimate of the influence of the use of power wagons will be extremely interesting, and will undoubtedly be valuable for all persons shipping or receiving freight, for the possibilities for relief of congestion at terminals will mean a great deal to every business man. The subject will be approached from an operating viewpoint

and with a purpose of suggesting relief from existing conditions, rather than advocating the use of any particular type or form of machine. Officials of various railroad and steamship lines have been invited to be present, as well as representatives of different civic bodies, and an interesting and instructive discussion is expected to follow.

BATTLING WITH ARMORED TRUCK.

The Mexican constitutionalists, of whom Gen. Villa is regarded as the chief warrior, are now using a two-ton Mack chassis, which has been fitted with steel armor and adapted for use on rails or road. The wheels are armored so that they cannot be damaged by rifle fire, and the body is constructed of sheet steel with an entrance at the rear, this resembling a conventional building because of the straight walls and the slanting roof, while the hood and radiator are protected by a dome that drops nearly to the axle and carries the lamps. The chains are shielded by aprons that are mounted on the sides of the body. The wheels are so built that in comparatively little time they can be changed for either road or rail propulsion. The machine is equipped with machine guns and these and the arms and ammunition are carried within the body.

MOTOR 'BUS LINE BANKRUPT.

The Rapid Transit Motor Company, which for more than a year operated a public service in Indianapolis, Ind., White chassis fitted with omnibus bodies being used, has been adjudicated a bankrupt, and the property disposed of. Four of the machines have been bought for public service at Akron, O., and another machine has been fitted for service on a Wisconsin railroad, it being equipped with Indestructible steel wheels made with flanges by the Indestructible Wheel Company of Lebanon, Ind., for this work.

DID THIS WITH A KISSELKAR.

In November, 1911, W. R. Knights, a Minneapolis, Minn., manufacturer, bought a 1500-pound KisselKar delivery wagon and placed it in service. Since that time the machine has been driven more than 40,000 miles, often with an overload, and it has not as yet required an overhauling or repairs of consequence. The wagon is driven an average of 13 miles to a gallon of gasoline and a set of pneumatic tires lasted about 3500 miles.

NEW BATTERY CATALOGUE.

The Electric Storage Battery Company, Philadelphia, is issuing a new catalogue, SL, describing the Exide battery utilized with automobile lighting and starting systems. It contains very complete information and data on the subject of batteries and will be forwarded on request.

NO WHEEL TAX FOR NEW YORK.

City's Corporation Counsel Opinion Is That Proposed Ordinance Is Illegal.

The owners of all vehicles used in New York City, and especially the owners of motor trucks, are keenly interested in the opinion of Corporation Counsel Polk of that city, to whom was referred a bill for an ordinance presented by President Marks of the borough of Manhattan, which was, in many respects, if not wholly, the same as the ordinance which was introduced in the board of aldermen of the city by President McAneny about a year ago. This opinion is in effect that the proposed ordinance is illegal and cannot be enforced if passed.

The ordinance as drafted was far-reaching in its scope, providing for the licensing of all vehicles and the payment of a tax ranging from \$1 to \$1000, the basis being the weight carried upon tires, 800 pounds to the inch of width being the maximum permitted save in special instances for which permits might be obtained. The fee was to be proportionate to the weight of the vehicle and the load carried with it, with reference to tire width, and according to the provisions some of the larger vehicles now in use would be taxed the limit of \$1000 a year, while others could not be used save by the payment of fees for special permits that would largely exceed this figure annually.

The purpose of the ordinance was to establish a wheel tax and create a fund by annual licensing which would be devoted to the repair of the street paving, and to effect this means were to be provided for licensing all vehicles, for a system of inspecting and weighing, with varying penalties for failure to comply with the ordinance. Means for identifying the vehicles and establishing their capacity were provided in the ordinance. There was no provision made for vehicles that might be used in the city by transients, and besides affecting all owners in the city itself, it comprehended a tax upon many thousands who reside or do business in the suburbs, including the residents of New Jersey and other states.

The opinion by Corporation Counsel Polk is

quoted as stating the following: "The authorities in which, under the power to regulate the use of streets, ordinances regulating the weight of loads and the width of tires have been upheld, involve enactments directed to the prevention of such use as would injure the streets or interfere with their convenient use by others. The ordinance at hand permits the injurious use upon condition that compensation be made therefor. This is tantamount to the levy of a tax. Under the general power of taxation for the purpose of revenue, property is assessed with reference to its value and under a complete system prescribed in the charter. I am constrained to advise you, therefore, that the ordinance submitted cannot be legally adopted by your board".

OHIO REGISTRATION TAX CONTINUED.

The Ohio motor vehicle owners who fought to a successful issue the constitutionality of the registration rates fixed by the Warnes law, will continue to pay the fees that prevailed prior to Jan. 1. After the decisions relative to the Warnes law endeavor was made to force the passage of a bill that heavily taxed the motorists, but this failed, and just previous to adjournment the legislators passed the King bill, which practically continues the old rates, the only increase being that of dealers, who will pay a fee of \$20 for a blanket license instead of \$10. Under the new law the rates will be \$2 for motorcycles, \$3 for electric cars or machines, and \$5 for gasoline vehicles.

The Mott Wheel Works, Utica, N. Y., has appointed A. D. Trempe sales manager and the R. B. Abbott Sales Company, Detroit, Mich., does not now control the sales of the company.

The Autocar Company, Ardmore, Penn., has leased the building at 753-5 West Jackson boulevard, Chicago, Ill., for 10 years and will occupy it as a salesroom and service station.

A regular quarterly dividend of 1.75 per cent. on preferred stock was ordered by the directors of the Packard Motor Car Company, payable on and after March 14.

Vulcan Trucks Ready for Delivery by the Vulcan Motor Truck and Service Company, Pittsburg, Penn.—From Left to Right: Two-Ton Covered Body for W. V. McCaffrey, Washington, Penn.; Two-Ton Chassis for the Atlantic Refining Company, Pittsburg, Penn.; Five-Ton Chassis for the Bellevue Contracting Company, Bellevue, Penn.; Three-Ton Chassis for the East Liberty Wholesale Grocery Company, Pittsburg, Penn., and a Five-Ton Dumping Body Equipped Truck for the Valley Sand and Supply Company, Parnassus, Penn.

BUYS 38 WHITE WAGONS.

Big Pittsburg Department Store Opened with Full Motorized Delivery.

The Kaufmann & Baer Company, which has just opened for business one of the largest department stores at Pittsburg, Penn., planned its store and its service from a knowledge of conditions, the enterprise being developed with a view of affording the people of that city and vicinity the best that could be provided with reference to value and attention. Because of the necessity of meeting competition in every direction, unusual care was given to delivery, and after careful consideration of this subject motorized equipment was decided on as being most economical and satisfactory, for time was regarded as a very important factor.

Pittsburg is built on the side of a river valley, where the grades are more than ordinarily steep, and the city is laid out in form that may be likened to a hand, the fingers and thumb being the different sections reached by main thoroughfares, with few connecting avenues. This necessitates vehicles returning from any one of these sections to what may be considered the palm of the hand, or the centre, to go to any other. The topography of the city is such that most of the loads taken out for distribution must be hauled up-grade, and a majority of the trips the vehicles must be driven light down-grade, this making the work more severe than would be expected in conditions usually met with. Not only this, but the mileage necessary in serving the city and its suburbs is considerably in excess of what might be regarded as necessary in other cities. Because of these factors haulage in Pittsburg has always been more expensive than in the majority of cities of the country, and larger horse equipment has been necessary because of the long mileage and the heavy grades.

In selecting its delivery equipment the company decided to adopt one make of machine for the reason that this would practically standardize the service, that men who were experts with this machine could be employed as drivers and mechanics, that this would minimize the stock of parts to be carried, that the

complications arising from inexperience with one of several makes would be avoided, and that the organization could be the better trained and systematized. An order was placed with the White Company for 38 wagons, 32 of these of 1500 pounds capacity, to be used for route and package distribution, and six 3000-pound wagons, for handling furniture and other bulkier goods, as well as hauling freight and other shipments. All of these vehicles were equipped with panel bodies and were identical in every respect, the difference being merely in size. All of the wagons are equipped with pneumatic tires, the 3000-pound machines having dual shoes on the rear wheels. The order was the largest ever given by a Pittsburg firm, and not only places the company in the position of being one of the largest users of motorized equipment, but among the leaders of department stores in delivery and transportation efficiency. When the machines were shipped from Cleveland, O., they filled an 18-car special freight train, and upon delivery, which event attracted not a little attention in Pittsburg, the company was in readiness to begin service with every probable requirement amply provided for.

The H. J. Koehler S. G. Company, 1709 Broadway, New York City, has published a very attractive and complete catalogue descriptive of the Koehler 2000-pound wagon, which illustrates the 10 types of body supplied by this concern, and gives a great deal of useful information relative to construction and equipment. Copies will be sent on request.

After a winter experience with a Palmer-Moore delivery wagon, the American Optical Company, Southbridge, Mass., ordered a second machine. The company expressed itself as perfectly satisfied with the service obtained with the vehicle and commented upon the prompt attention of the maker to all matters referred to it.

The purpose of the Hydraulic Truck Company of Los Angeles, Cal., if present plans are realized, is to establish a plant in Colton, Cal. W. E. Barnes is president of this company and D. L. Whitford is the general manager.

The Fleet of 38 White Delivery Wagons Purchased for the Service of the Kaufmann & Baer Company's Department Store, Pittsburg, Penn.

NO PRACTICAL MOTOR TRUCK FENDER.

Every Type Tried in America and Europe Increases Danger in Traffic Instead of Affording Protection--Innumerable Inventions Absolute Failures.

AN INJURY or fatality resultant from a motor vehicle striking a person in its path immediately causes the assumption by a very large proportion of the public that protection should be afforded by equipment carried by machines. The thought is perhaps logical, but how this condition can be met is a subject that has received a great deal of attention by those who have the welfare of the public, the motor vehicle industry, and the owners of the machines to consider.

The prevailing opinion appears to be that pleasure cars, which are driven at fast speeds, should not be required to afford the same degree of safety demanded from freight vehicles, which are rarely driven fast and are almost universally better controlled. Facts that are given with relation to highway traffic accidents seldom, if ever, differentiate between the two classes of vehicles. Surprising as this may appear the people apparently think that if a pleasure car is involved in an accident there is a question as to the responsibility, but if the vehicle is a truck or wagon the conclusion is that the driver was at fault and that the public ought to be better protected.

This decidedly hazy condition of public opinion relative to traffic accidents, and the agitation that may follow a singular or peculiar circumstance, has been in large measure responsible for local legislation, or at least proposal of such, as will necessitate fender equipment on freight motor vehicles. Those who own and drive pleasure cars, who no doubt drive as rapidly as the law will permit, who would not for a moment consider a proposition to equip their cars with fenders, seemingly approve measures that would cause the installation of such devices on machines owned by others, or at least do not oppose them. The owners of motor service wagons are a comparatively small number in any community, and remonstrance to any proposal to compel the use of fenders is regarded as antagonistic to the general welfare, no matter how logical or sane these objections may be. In other words, the public assumes that the owners of motor trucks and wagons seek opportunity to injure people and take life rather than pay the cost of what would protect.

The first municipality to enact an ordinance requiring fender equipment was Detroit, which has recently repealed this measure, and this was followed by a similar ordinance enacted in Chicago. Later on an ordinance offered in the Cleveland, O., city council was not favorably reported by the committee to which it was referred, and the Milwaukee, Wis., city council rejected an ordinance having practically the same purpose.

The experience with the ordinances of Detroit and Chicago has been followed very carefully by the industry and its various organizations, as well as the industrial and trade press, with a view of ascertaining the results from the practical utilization of such fenders as have been developed. Broadly, it may be stated that no satisfactory fender has yet been conceived, and this is in line with the experience abroad, where

Diagram Showing the Additional Space Required in Traffic by a Five-Ton Truck Fitted with a Fender Extending 28 Inches, This Covering a Radius Two Feet Greater, with the Extreme Projection Concealed from the View of the Driver.

the English, French, German and Italian governments exercise a much more rigid supervision and insist upon extremely careful observance of all regulations intended to afford safety.

The desire for greater protection may inspire city councilmen or others to advocate the use of fenders without a practical knowledge of the subject, and the absence of sufficient and definite information may lead to the enactment of ordinances that will be ineffective as to results; will cause material expense to motor vehicle builders, dealers, owners and operators, and will possibly involve the question of responsibility.

The possibilities from agitation of fender equipment has impelled the National Automobile Chamber

of Commerce to learn from service vehicle manufacturers and users in Detroit and Chicago the effects of the ordinances, and the opinions as to the practicability of fenders as applied to machines in those cities. No one of more than 20 responses to inquiries has been favorable to the use of fenders, and practically all point out the inefficiency of those that have been tried, as well as the possibility of increase of accidents through their use. Emphasis is made that both the Detroit and Chicago ordinances were enacted hastily and despite the facts that no fender had been proven sufficient and none could be built in sufficient numbers to meet the demand in the time allowed for equipping the machines.

The Detroit ordinance is:

Section 1. That all persons, firms or corporations now and hereafter owning or operating motor vehicle trucks of one-ton capacity or more in the City of Detroit, shall provide all their cars now or hereafter in use with fenders designed to catch and sustain any human being who may be in the way of such car, and so mechanically constructed that such fenders may be lowered or raised by the operator in charge of said motor vehicle truck, or such other fenders as may be deemed best to carry out the intent of said ordinance, such fenders to be of such design as the police commission shall have certified in writing to meet with their approval.

Sec. 2. It shall be the duty of the police commission to examine and pass upon all designs of such fenders submitted to them by any person, firm or corporation owning or operating any motor vehicle truck within the City of Detroit, and give written certificate to such applicant of his approval or disapproval of such designs.

This ordinance provides that a fine of not less than \$10 and not more than \$100 may be imposed for every day a vehicle is operated in violation of the regulation, or a penalty of 90 days' imprisonment in the house of correction for each offense may be inflicted.

The Chicago ordinance provides as follows:

Sec. 2650½. It shall be unlawful for any person, firm or corporation to use and operate in the City of Chicago any auto car or truck for the purpose of conveying therein bundles, parcels, baggage or wares, merchandise or other similar articles, unless said auto truck or car is provided with a fender as in the case of street cars operated and used within said city, or such design as may be approved by the board of inspectors of public vehicles.

In Detroit the ordinance became effective Oct. 1, but upon representations made by truck owners the time was extended to Nov. 1 by the police commissioner, because he could not approve any fender submitted, and later extended to Jan. 1 by the same officials. After that time endeavor was made to enforce it, but it caused such hardship for motor vehicle owners because of the impossibility of obtaining a satisfactory fender, that in March the ordinance was repealed. The experience of the police commissioner was that there was no apparent diminution of accidents because of the use of fenders.

The experience with reference to approving fenders that might serve the purpose specified in the Chicago ordinance was much the same as in Detroit, and from the fact that no fender could be found that met the requirements, and to enforce the ordinance would mean the practical cessation of service vehicle use and result in extreme hardship for business men, no attempt has been made to enforce it. But the agitation resulting from the ordinance has brought about the creation of a traffic commission that is studying

street congestion and accidents with a view of recommending measures that will afford relief.

Those who have observed conditions and studied the subject of fenders are very generally united in criticism, which may be summarized as follows:

That such fenders as are now available are as likely to cause injury or fatality as to prevent, that they increase traffic confusion, that they are easily damaged and made inoperative, that no satisfactory or effective type of fender is known to truck builders or users, and that there is no more need for such equipment on trucks than on pleasure cars, wagons or motorcycles.

In connection with this an analysis of the records of street accidents in Cook county, made by the coroner of Chicago, is of interest, from the fact that this established the fact that motor vehicles have caused about half the number of deaths resultant from horse vehicle accidents when the number of miles travelled is taken as a basis.

An investigation of the records of deaths from motor vehicle accidents in Milwaukee, made by the Stegeman Motor Car Company, showed that only about 10 per cent. were caused by motor trucks, and that in no instance would fenders have prevented death, as the victims fell between the front and rear wheels.

The Pierce-Arrow Motor Car Company has published a pamphlet dealing with the subject in which are summarized arguments for and against the use of fenders, prepared by its engineering department, and this is being distributed to those who are desirous of learning facts that should receive consideration. Statement is made that a fender that would save life, provided that it was made in a manner and of material that would endure, could be easily applied and kept in good repair, would be welcomed by all. Such a fender would be adopted, but legislation compelling the adoption of any unproven device that might be offered for the purpose is deprecated. The report of the public service commission for the first district of New York State, which was published Dec. 29, 1908, on car fenders and wheel guard tests, is referred to. This report can be purchased at 150 Nassau street, New York City. The report deals with tests made with life size dummies, very carefully made to represent actual conditions, with the comment that these trials were with street cars running over a fairly good roadbed in a fixed direction. The comment is made that the gist of this report is that very careful and elaborate tests should be made before deciding on a fender, and that many fenders which would seem to be valuable were more dangerous than if not used.

The following statement is made relative to the use of fenders on trucks, and the instance referred to is diagrammatically presented. As illustrated the sketch shows a fender, designed by a well known concern, that projects 28 inches in front of the machine, which is 78 inches width, and this adds 12 per cent. to the overall length of the Pierce-Arrow truck and 15

per cent. to the overall length of the two-ton wagon. This is objectionable in that it is added at a point in front of the driver. On the five-ton truck the driver's eye is 11 feet away from the fender extremity, and by reason of the radiator, mudguards, etc., obstructing his view, he is not able to judge of the wisdom of dropping the fender or not. The statement continues:

Again, how is he to drop his fender? One hand is on the steering wheel; the other at the brake lever; a foot on the clutch pedal and another on the brake pedal. He must be a wise, cool-headed driver who would remember what to do in an emergency.

To our mind, the greatest danger lies in the projection of the fender when turning corners. The driver's attention is concentrated in the direction at right angles to where his fender is probably breaking a traffic policeman's leg. Besides one wheel is left unguarded at this operation. On our five-ton truck, a straight fender nearly 13 feet wide would be required to thoroughly guard the track. A curved fender would be somewhat shorter but horribly complicated.

A device which does not fit closely to the ground is not a life guard—it is a trap. It is practically impossible to drop a fender closely to a rough road without its being damaged by the road to such an extent that it is quite conceivable it would present a jagged, spiked weapon to the unfortunate victim, instead of a comfortable couch.

Most people would rather take a chance and take advantage of the 12-inch clearance between the wheels of a truck than of being hit with any fender seen yet.

A fender would certainly trip them up and throw their heads against the radiator with some force instead of rebuking carelessness in a gentle manner.

In conclusion, let us read a letter under date of Dec. 19, 1913, from Mr. Iden, chief engineer of the London General Omnibus Company, which, you will remember, runs about 3000 omnibuses through very congested traffic. The damage claims of this company are such that it is very earnest in its search for a real life saver.

"In reply to your letter of the 4th instant, during the past year we have made up and tested a number of front guards, but we regret to say that up to date we have not found one efficient enough to warrant fitting to our 'buses'.

"The early types of lifeguards, which we tried, were more in the nature of fenders or gates, but these were found unsatisfactory in cases where a person had fallen prone when the limbs were invariably drawn under the guard, and more damage was done than if there had been no guard and they had been run over by the wheel.

"We have tried a trip guard similar to that used on tram cars, but this, to be effective, had to have too great a projection to allow us to adopt such a device.

"Other types of devices have been in the nature of brushes constructed to sweep the person in front or aside. This was very unsatisfactory, as it collected so much road refuse, besides in dry weather creating such a dust that it was impossible to leave such a device on the 'bus'.

"So far, the most effective device which we have tried has been in the nature of a rubber covered wheel, which is held against the road wheel by a slight spring and, being in contact with same, caused the rubber covered wheel to rotate in a reverse direction, thus, when this met an object, it would tend to roll it away rather than draw it in under the wheel.

"All our earlier devices were of our own design, but latterly we advertised in all the leading journals for suggestions and, as a result, received 4700 replies and, included in these, was the one with the wheel rotating in the reverse way to the road wheel, as before mentioned, but other than this, no suitable guard was found among all the devices submitted".

Mr. Iden added a postscript that the wheel referred to is not sufficiently good for them to use.

In connection with the sketch illustrating the article it will be noted that this shows the possibility of a fender projecting two feet or more over a curb, if it were not so low as to strike it, outside of the curve made by the wheels, and this condition always obtains when turning. And unless the fender were increased in width it would not protect against the inner front wheel when turning short. Fenders must have several inches clearance to provide for rough roads, crossings, car tracks and other ordinary road obstructions. In the event of a fender being damaged it cannot be made operative immediately, and this means the loss of the service of the vehicle.

But no fender will protect against violently strik-

ing some other parts of the vehicle, for the wheels are not the only parts to be feared, and these would not in any way protect against a person falling between the wheels.

WILL EXPORT FROM BOSTON.

Plans have been perfected by which the Lauth-Juergens motor trucks and wagons will be exploited in the West Indian Islands and South America, and the shipments exported will be made by the Myer Abrams Company, 159 Vassar street, Cambridge, Mass., the New England distributor. The agencies have been established in a number of the principal West Indian and South American ports and arrangements made so that the purchasers of the Lauth-Juergens machines will be afforded a practical and satisfactory service.

Samuel Rolfe has been appointed sales manager of the Signal Motor Truck Company, Detroit, Mich., resigning a position as district sales manager for the Federal Motor Truck Company of the same city, which he had held for several years, to accept the appointment. He is now engaged in making new agencies for the Signal machines.

During the Boston motor truck show the Peerless Motor Car Company of New England, distributor of Peerless cars and trucks, did not make exhibition, but instead had a special display of service machines at its headquarters at 660 Beacon street. The showing included practically every type of Peerless machine built.

At the annual meeting of the Driggs-Seabury Ordnance Corporation, Sharon, Penn., John Stevenson, Jr., was re-elected president, William Flinn of Pittsburgh vice president, R. S. Pratt secretary and Harry Myers treasurer. The board of directors was unanimously re-elected.

If a bill now pending in the New York legislature becomes law 13 or more owners of motor vehicles not used in trade or manufacture or operated for hire may incorporate for the purpose of insuring on the mutual plan against damage, accident or legal liability.

The plan of Postmaster Nagle of Detroit, Mich., to abandon the use of animals for delivery and collection for the postoffice of that city and to completely motorize the equipment in use, has been approved by the departmental authorities.

Edward H. Busby, well known in the industry and trade, has resigned as sales manager of the Anderson Forge & Machine Company and has been appointed general sales manager of the Ferro Machine & Foundry Company, Cleveland, O.

EXPLOSIVE-CARRYING TRUCKS.

The oil fields of Oklahoma include a large area of country that has been but little developed. The possibilities for finding petroleum has caused a great deal of prospecting, however, and this search for oil has been in any direction that fancy or indication directed. When wells have been drilled they are generally in localities sparsely inhabited, and sometimes remote from towns. The drilling of wells necessitates carrying material and supplies sometimes long distances, frequently over country that has hardly a trail, and haulage is not only difficult, but considerable time is required.

After wells have been drilled it is occasionally necessary to explode nitroglycerine in them with a view of starting the flow of oil, and for this reason considerable quantities of this high explosive are carried about to the different places where work is in progress. To do this work with horses is costly and dangerous, and for this reason the companies that manufacture and distribute nitroglycerine have found it advisable to use vehicles that would be more thoroughly under the control of the driver, as well as having long mileage. That is, they have taken kindly to motor wagons, which have been specially equipped so that the explosives may be carried without danger.

The American Glycerin Company, with headquarters at Battersville, Okla., has now in use five Adams 3000-pound wagons, which have been built expressly for this work. The machines have 42-inch wheels, which gives large clearance on the rough roads and cross country hauls, and the chains are enclosed to prevent wear and to avert danger. The bodies are of the express type, but are fitted with special boxes that have covers that may be locked and are divided into compartments, each of which will carry a single can. The capacity of the wagons is 720 quarts. With loads that have sufficient explosive energy to devastate a

large area if exploded, these machines are driven hundreds of miles each month, covering rough country, in all kinds of weather, and giving the best of satisfaction.

CABOT MECHANICAL RECTIFIER.

The Cabot mechanical rectifier, designed by Sewall Cabot, a well known electrical engineer, was described and demonstrated at the March meeting of the New England section, Electric Vehicle Association of America, which took place March 25 at the office of the Lynn, Mass., Gas & Electric Company, with James F. Dubois as the host.

The possibilities for the machine were told of by Mr. Cabot. It is a rectifying commutator similar to a rotary converter, but without moving parts. The claim is made by the inventor that a rectifier of 100-ampere capacity will operate at unity power factor with efficiencies of approximately 20, 18 and 12 per cent. more comparatively than the motor-generator set, the rotary converter and the mercury arc. After the address the machine was discussed to considerable length.

Announcement was made that at the May meeting Frederick Hortter, car accountant of the Boston & Maine railroad, would discuss traffic problems. The date and place of meeting have not been determined.

PACKARD TRUCK BASEBALL LEAGUE.

The motor truck sales organization of the Packard Motor Car Company has been constituted the Packard Truck Baseball League, which began its season March 1, and is now striving for a pennant and a \$500 bulldog. The league consists of 10 teams that compete three times with each other during the season. The "players" have signed contracts and all the formalities that are regarded as essential to organization have been carried out. In the competition sales are recorded as runs, and the team making the largest score during the period is the winner. The managers are: President Henry B. Joy, Vice President A. D. Waldon, General Manager Alvan Macauley, Sales Manager H. H. Hills, President of Branches M. J. Budlong, Consulting Engineer Russell Huff, Alvan T. Fuller of Boston, Cuyler Lee of San Francisco, Earle C. Anthony of Los Angeles and Ginder Abbott of New Orleans. Results of the progress of the competition are published in the "Packard Winch", which is issued daily.

Adams 3000-Pound Wagon Used for Distribution of Nitroglycerine in the Oil Fields of Oklahoma, Fitted with Special Equipment.

GOODYEAR OFFICES UNITED.

The Goodyear Tire & Rubber Company has determined to consolidate its sales department in New York City with a service station at Long Island City, and the selling organization will be removed from 1972 Broadway and located at Honeywell street and Jackson avenue, in a new building that will be ready for occupancy next month. The new station is of large proportions, it being a six-story and basement steel and concrete structure with 270 feet frontage. The equipment will be complete, and the station will be prepared for any work that may be required by customers.

FORMAL DISSOLUTION EFFECTED.

The supreme court for New York county, New York State, has granted an order of dissolution for the Automobile Board of Trade, which has been succeeded by the Automobile Chamber of Commerce, Inc., every formality having been complied with, and the organization existing in name only. The Automobile Chamber of Commerce has now possession of the records and property of the Association of Licensed Automobile Manufacturers and of the Automobile Board of Trade and the National Association of Automobile Manufacturers.

Harry M. Snyder, secretary of the Reo Motor Truck Company, and secretary and director of the Reo Motor Car Company, Lansing, Mich., has resigned those positions and will spend the next year in travel and recreation. He has been prominent in the industry for about 12 years.

The American Bronze Company, Berwyn, Penn., has plans perfected for the immediate erection of buildings that will increase the foundry capacity 40 per cent. and the finishing department 75 per cent. A recently completed and finely equipped laboratory is now in active use.

T. B. Waller has been appointed assistant general manager of the Lincoln Motor Truck Company, Sacramento, Cal., which is to manufacture the Lincoln truck. He was formerly connected with the Lincoln Motor Sales Company, Seattle, Wash.

The Jackson Metal Products Company has been organized with John Stern as president and L. M. LaDuke vice president, and is to locate at Jackson, Mich. It is to specialize the production of fenders, radiators, etc., and is said to have abundant capital.

The Federal Motor Truck Company, Detroit, Mich., has appointed R. P. Spencer, formerly associated with a well known Milwaukee industry, sales and advertising manager. He has assumed the duties of the position.

ONE SHIPMENT OF 38 TRUCKS.

The White Company, Cleveland, O., recently made what is believed to be the largest single shipment of motor trucks ever sent out from a factory, this consisting of 38 vehicles contained in 19 box cars and consigned to Pittsburg, where the machines are now in service. The train as made up was 700 feet long.

SCHMUNK MADE SALES MANAGER.

R. J. Schmunk, after service of about seven years with the Peerless Motor Car Company, Cleveland, O., has been made general sales manager, in which capacity he is executive of the entire selling organization of the concern. He has been associated with the industry since its inception and has been connected with several concerns in different parts of the country, most of the time devoting his endeavors to selling. Because of the nature of his work he has become known to thousands of motor vehicle dealers in all sections of the country.

When he joined the Peerless organization he was a salesman, but within a short time he was advanced to sales manager, in that capacity having charge of the distribution of pleasure cars.

About a year ago he was made director of sales, and he continued in that position until his last promotion. He now handles the sale of both pleasure and service vehicles.

R. J. Schmunk, General Sales Manager, Peerless Motor Car Company.

PIGS RIDE IN TRAILER.

Novel uses are sometimes made of motor vehicles, but one that is amusing is that adopted by T. E. Ely, Brewster, Minn., who is known throughout the northwest as a raiser of blooded porkers. He has a piggery that covers a large area and he sells his stock in all parts of the country. Shipments by railroad are frequent and are made in the usual way by car, but where a customer is within a reasonable distance, or an exhibit is to be made at a fair, one or more pigs are placed in a special trailer that is drawn behind Mr. Ely's motor car and hustled over the road at comparatively small expense.

CROSSING THE HUDSON.

Motor Truck Club Members Hear Projects for Bridge and Tunnel Explained.

The North or Hudson river is between the business interests of New York City and the railroad and shipping terminals that extend along the New Jersey shore in Jersey City, Hoboken and Weehawken, the only connection between the two for vehicles being the different ferries, most of which are operated in connection with the railroads. For passengers there are the Hudson tubes, which have diminished pedestrian congestion, but the increasing volume of business has been profitably taken care of by the ferries.

The use of the ferries has had the effect of concentrating the vehicles used for passengers or for freightage between Manhattan and New Jersey in certain streets of the Metropolis, and in the cities on the Jersey side, and because of the necessity of loading and unloading, as well as transit, these have been practically blockaded for years, while the piers and terminals have been congested nearly to the same extent as in New York City.

The conditions have been realized and understood for years, and different propositions have been made for permanent relief, but generally these were theoretical rather than practical and could not be brought about save through the expansion of terminal and dock facilities, which is impossible save at enormous expense and the co-operation of the State of New Jersey with the national government and the municipalities and the owners of the properties.

The Motor Truck Club of America, at its meeting March 18, to which were invited the members of the Electric Vehicle Association of America and other organizations having similar interest in the better regulation and systematization of street traffic, listened to explanation by members of the New York State bridge and tunnel commission, and the New Jersey interstate bridge and tunnel commission, of the proposed bridge and tunnel between Manhattan and Jersey City. The meeting, which was at the Automobile Club of America, was largely attended and much interest was manifested.

The plan as proposed comprehends the construction of a tunnel at Canal street, or near that point in New York City, extending to Jersey City, and a mammoth suspension bridge from 58th street and Eleventh avenue that will cross the river about 3.5 miles above the tunnel, both to be largely for the benefit of vehicular traffic. The tentative projects were illustrated, sketches and plans being shown on a screen by stereopticon, these being explained by the engineers.

The possibilities for economy and better facilitating the handling of freight, as well as the financial aspects, were explained by Senator Martin Saxe, counsel for the New York State bridge and tunnel commission, and by Senator J. A. C. Johnson, counsel for

the New Jersey interstate bridge and tunnel commission. The cost of the bridge is estimated at \$42,000,000 and of the tunnel \$11,000,000, making a total of \$53,000,000 for the two. It is proposed that the expense shall be largely, if not wholly, borne by the two states that will be connected. Bills authorizing the construction and the financing of the work are now pending before the legislatures of the states.

According to the plans suggested, and which will probably be recommended, the bridge will be 1.57 miles in length and will have a single span of 2880 feet, which is about 1100 feet longer than the longest single span ever constructed, but as an engineering possibility it is regarded as very practical. The main piers will be 555 feet in height, or as high as the Washington monument, above the bedrock foundation, and 350 feet above tide water, the total width will be 204 feet, and the clearance will be 175 feet above high tide. The proposition is to have a single deck which will support the roadways and railroad tracks, with wide sidewalks at the sides. At the New York side the approach to the bridge would have a three per cent. grade, and it would be level on the New Jersey side. The plan was described by Henry W. Hodge and C. D. Snyder of Jacobs & Davies, they representing the engineers for the two commissions. The tunnel was described as approximately 1.75 miles in length, to consist of twin tubes 14 feet high and with 17-foot roadways, with maximum grade approaches of three per cent., and with large elevators that would hoist and lower from the street levels to the roadways or vice versa the vehicles that were to go to points on the river fronts. The estimate of actual time saved in crossing was from 10 to 15 per cent. of that now required for ferriage. As it is estimated that about 6,500,000 vehicles are annually carried by the ferries, the aggregate of time economy alone is enormous.

The Automobile Equipment Company has been incorporated at Cincinnati, O., with capital of \$100,000, by George W. Platt, Arno Merkel, H. E. Maffey, M. L. Freeman and Alice DeCharmes, to manufacture and deal in automobiles and motor trucks.

The Hoboken & North Hudson 'Bus Transportation Company has been incorporated at Hoboken, N. J., by W. O'Neill, W. A. Kavanagh and E. F. Martin, with capital of \$1,250,000, and will engage in a general passenger and freight transportation business.

The Merchants' Motor Truck Manufacturing Company has been incorporated at Chicago, Ill., with capital of \$100,000, by W. Schulze, J. W. Misk and C. A. Martin, under the Delaware law, and will manufacture and deal in motor trucks, motor vehicles, etc.

At the annual meeting of the Vacuum Oil Company at Rochester, N. Y., the charter was extended for 50 years and the old board of directors was elected.

STATES REJECT UNIFORM MOTOR VEHICLE LAW.

WHAT was believed by some to be a promising opportunity for the enactment of a reasonably uniform motor vehicle statute by a number of the eastern states has disappeared, and apparently the endeavors of those who devoted time and study to the subject have been wasted, simply because of assumption that the activities of those interested in it were not authorized by the different states. That is, this was the primary argument made by the legislators who received the report made by the committee that represented the different states. Had the committee been named by the authority of legislative action in each of the states there would have been necessity for recognition of the report, but the manner in which the committee was appointed, and the fact that the members acted without definite instruction, being actuated by their own judgments, afforded opportunity for those who assumed their own rights encroached upon to nullify the endeavors of the committee.

The committee was composed of Secretary of State Albert Phillips, Highway Commissioner Charles J. Bennet and Alfred H. Terry of Connecticut; Judge Sylvester Townsend and Charles S. Guyer of Delaware; Attorney-General Scott Wilson, Lyman H. Nelson and J. C. Scates of Maine; Chairman William D. Sohler of the state highway commission of Massachusetts; Highway Commissioner Harry Roe, President H. M. Rowe of the Automobile Club of Maryland and H. M. Luzius of the same organization of Maryland; Samuel W. Taylor, Fay C. Parsons and A. J. Deer of New York; Motor Vehicle Commissioner Job H. Lippincott, Highway Commissioner Edwin A. Stevens and George L. Burton of New Jersey; Highway Commissioner E. M. Bigelow and Robert P. Hooper of the Pennsylvania Motor Federation of Pennsylvania.

The committee members were assumed to be appointed by the governors of the eight states named, and that there was sufficient sincerity and actual interest obtaining on the part of the legislators to justify consideration of a law that would be uniform and, from this point of view, materially beneficial to the motorists and the people. The committee held several meetings and discussed the subject carefully. A report was prepared, first in preliminary form, and after consideration and revision this was adopted with the recommendation to the legislatures that it had the approval of the representatives of the different states. While the report may not have been ideal from the viewpoint of the owners of motor vehicles, there is no doubt that it was a distinct advance as compared with the statutes of the states as a whole, and in addition to this it afforded a much better protection to the people from the fact that the weaknesses were corrected and that one might drive for hundreds of miles with absolute knowledge of motoring regulations and requirements. Not only this, but sufficient penalties were provided for violations so as to insure that

the provisions of the law shall be strictly observed.

The reports made to the different legislatures by the committee were received, considered by committees and invariably rejected, the value of the uniform statute, which was one of the chief reasons for the consideration of the subject, being disregarded, and trivial or inconsequential arguments made to controvert the real purpose of the measure, which was designed to meet every condition broadly. The experience of the men who devoted their time and attention to the study and investigation of the proposition, purely for the benefit of the public, is such that there is small probability that they would care to repeat their work, and they are generally in a frame of mind that the word disgusted mildly expresses.

WANTS \$66,666.37 FOR TRUCKS.

Herman A. Metz, formerly comptroller of New York City, a former congressman, is the defendant in a suit brought by the R. & L. Company of New York, distributor for Garford trucks, the plaintiff seeking to recover a balance of \$66,666.37 which is claimed to be due for the balance of the purchase price of 65 trucks in the service of the New York Mail Company.

The New York Mail Company was contractor to carry some of the mail in Manhattan south of 42nd street, and it disposed of the greater part of its horse equipment and purchased trucks. The contract expired June 30, 1913, and the contract was awarded to the Postal Service Company. The New York Mail Company was supposed to be a heavy loser through the contract. The defendant in the action is claimed by the plaintiffs to have had a substantial interest in the company.

The Precisions Kugel Lager Works, Fichtel & Sachs, maker of the F. & S. bearings, for which the J. S. Bretz Company is American selling agent, sold Feb. 1 its 33,000,000th set of ball bearings. The company was founded in 1904 by Ernst Sachs, the patentee of the bearing, and it now has factories that employ 4000 workers.

E. M. S. Young, formerly manager of the Superior Steel Company, Carnegie, Penn., and general manager of the Alleghany Steel Company, Brackridge, Penn., has been made general manager of the Standard Gauge Steel Company, Beaver Falls, Penn., and John J. Tyler has been made director of sales of the same concern.

William H. Nash, formerly with the McClernan Steel Company, Chicago, and W. K. Prudden of Lansing, Mich., has been appointed selling representative at Detroit, Mich., for the Mott Wheel Works of Utica, N. Y., with offices at 809 Woodward avenue.

BUYS 105 KELLY TRUCKS.

Big Order for Machines for Passenger Service in Southern California.

The Pacific Motor Coach Company has, according to the statement of the Kelly-Springfield Motor Truck Company, Springfield, O., ordered 104 special five-ton truck chassis and one two-ton chassis, a total of 105 machines, which are to be used in passenger service in Southern California.

The Pacific Motor Coach Company has been organized at Los Angeles with capital of \$500,000 for the purpose of establishing motor vehicle transportation service lines between different towns and cities in the lower section of the state, and to inaugurate these as quickly as the equipment can be delivered. The executive offices are to be at Los Angeles and the machines will be of the double-deck type used abroad and in New York City and several other American municipalities.

A number of the lines will radiate from Los Angeles, serving Venice, Long Beach, San Pedro, Pasadena and other suburbs and residential sections. Others will serve more distant points. The first lines will be in operation by July 1 and the company hopes to have all of the machines in use by Jan. 1. Of the chassis ordered the five-ton machines will be used for passenger work, and the two-ton chassis will be equipped with a gasoline tank and will distribute fuel to the different stations.

R. G. Munn is president of the Pacific Motor Coach Company and Murray A. Harris is vice president. After considering the Kelly machines in Los Angeles they came East, and passed five days at the factory at Springfield, O., and then continued on to New York City, where the sale was consummated. The first 33 chassis will be delivered as quickly as possible, and the others will be shipped on a monthly schedule.

REO FACTORY ACTIVITIES.

The plant of the Reo Motor Truck Company, Lansing, Mich., is now being worked to its full capacity, and some departments of it overtime, to meet the demand for the model J machines, and this despite the fact that last autumn a large amount of machinery was added to the equipment and preparations made for producing the trucks in much larger numbers. The pleasure cars are now produced at the rate of 65 a day, and shipments have been as high as 90 in a day. The factory now has more than 2000 orders for April delivery.

The assets of the Cleveland-Galion Truck Company, which include the plant at Galion, O., have been purchased from the receiver of the concern by the stockholders, who purpose to rehabilitate the concern. The company builds an electric internal freight truck.

WANTS CONVICT-MADE BRICK ROADS.

Governor Glynn of New York proposes that the state shall build roads that will be with such surfacing that they will endure from 20 to 30 years and will cost but trifling sums for maintenance. He stated in a message to the legislature that the state must either change its policy, or prepare a perpetual yearly road tax of \$2 on every inhabitant of the state. This meant a translation from highways such as are now built, having an estimated endurance of 10 years and costing \$1000 annually to maintain, to those that will endure for two to three times the period and cost from \$10 to \$60 a mile. He believed it would be economy for the state to build brick roads at a cost of \$25,000 a mile instead of macadam roads in all places where the motor vehicle traffic is large.

The state issued bonds to the value of \$50,000,000 to build 12,000 miles of state road, these to run for 50 years, and as the roads are now constructed Governor Glynn believes that they will be in need of reconstruction 40 years before the bonds to pay for the original work will mature. He believes that while the concrete road costs from \$2000 to \$3000 a mile more than high grade macadam, and brick roads from \$10,000 to \$12,000 more a mile than macadam, the saving of the brick construction would be very large. He makes a proposal to establish camps of convicts in connection with plans for the making of vitrified brick to be established by the state, so that, without the normal expense for brick the cost of brick roads may be reduced to a figure not greatly in excess of macadam.

FUTURE OF MORA COMPANY IN DOUBT.

The future of the Mora Power Wagon Company of Youngstown, O., which has been in the hands of the courts since December, has not been determined, and there is no immediate prospect of a settlement. Frank H. Adams, treasurer of the company, was made receiver upon his petition, but a counter petition made by S. H. Mora, the promoter, which specified an error in the service of the original papers, was later presented and the first decision was reversed and Mora was made custodian of the property. The statement that Youngstown capitalists have secured control of the company and will remove it to Cleveland, O., is maintained to be without foundation.

The National Carbon Company, Cleveland, O., maker of dry cells, has purchased a tract of land 200 by 600 feet, bounded by Manley and Orton streets and Thompson and Mott avenues at Long Island City, N. Y., and will erect a factory building that will cover the entire property.

A factory building to be located at Colton, Cal., has been contracted for by the Hydraulic Truck Company of that place.

USED MOTOR WAGONS 12 YEARS.

The Joseph Horne Company, Pittsburg, Penn., which operates one of the largest department stores in that city, and has 55 machines in its service, began with its first motor vehicle more than 12 years ago and constantly increased its equipment until it was completely motorized. This concern was one of the first in the country to utilize motor wagons, and its experience has proven the economy and better service that is practical with them.

The company has provided every facility for storing and maintaining its fleet of machines, having a garage that has 15,000 feet of floor space, located in the centre of population of the Pittsburg district, which is extremely advantageous for expeditious delivery. The building is designed to provide for future requirements as far as these may be foreseen, and is constructed of steel reinforced concrete and is fireproof. The equipment is the best that experience has taught is available for care and upkeep and includes a repair shop with a full installation of hand and machine tools, blacksmith and brazing departments, a tire repair shop with a large vulcanizing outfit, a fireproof oil storage room and a 1000-gallon air-pressure gasoline storage system. In the building there is a large mezzanine floor on which are a dining room, a rest room, spacious lockers and the best of toilet accessories.

HUTCHINSON JOINS STERNBERG.

Rollin W. Hutchinson, who was advertising manager of the International Motor Company, and later was associated with the transportation engineering department of the Packard Motor Car Company, has been appointed general sales and advertising manager of the Sternberg Manufacturing Company, Milwaukee, Wis. Mr. Hutchinson is well known in the East, for a considerable length of time being a resident of New York, and he was identified with the National Motor Truck Club of that city. Mr. Hutchinson has attracted some attention recently by a broad criticism of the motor truck and wagon manufacturers for not supporting to the fullest extent the widely directed promotive endeavors of the Motor Truck Club, and has advocated the formation of a national association of motor truck manufacturers along similar lines to the Electric Vehicle Association of America, which, he maintains, would serve a very useful purpose and directly benefit the industry.

With the purchase of 10 White taxicabs the Cleveland, O., Taxicab Company now has 18 of these machines in active service. The company was organized two years ago and began business with six machines, and after about a year's experience with these ordered two more. Because of the satisfaction obtaining with the cabs and the increase of business the latest order was decided on.

ADJUSTMENT FOR DEFECTS ONLY.

Some of the Tire Manufacturers Considering Abandoning "Mileage" Basis.

While no decision has been reached as yet, some of the largest manufacturers of tires are said to be considering a proposition to abandon making adjustments on the basis of mileage, and to confine their guarantees against such defects as will reduce the serviceability of the tires, just in the same manner that most other manufacturers guarantee their products against faulty workmanship or defective material. The application of this policy is not stated, but it is assumed to be with reference to pleasure vehicle shoes, for the companies that are recognized leaders in the industry in January established a lower rate of guarantee for mileage for motor truck and wagon tires.

The claim is made by the tire manufacturers that were it not for the guarantees they would undoubtedly sell tires for lower prices, and they would willingly protect any purchaser against whatever defect might result from poor material or bad workmanship. But to say that a tire shall yield a specific mileage in any conditions is not reasonable and the supposition that a guarantee may be given leads to neglect and abuse that is extremely costly and must in the last analysis be paid for by the people who use tires.

When a tire is sold with a guarantee of mileage the purchaser naturally assumes he is entitled to all he pays for, despite the conditions for use, and demands that he be given adjustment on the basis of sale. The experience has been that facts are economized and claims made with the expectation of obtaining whatever may be due from the viewpoint of the purchaser. Business competition has impelled such adjustment as may satisfy the user, even when imposition is realized, and when there is reasonable knowledge of this.

The belief is that were the guarantee simply confined to factory imperfections that would reduce the normal wearing qualities of a tire, and the owners required to provide their own guarantee by driving with such care as would be expected with tires that were susceptible to damage, they would exercise such care or supervision as would afford them good results and at a comparatively lower price. Statement may be made that the price of rubber is advancing, but this is not as yet a factor that will influence a change in the market price of tires.

The Chr. Heurich Brewing Company, Washington, D. C., has decided to motorize its transportation department and will install as its standard equipment the Vulcan trucks, made by the Driggs-Seabury Ordnance Corporation, Sharon, Penn., giving an initial order for one each of the two, four and five-ton chassis, which will be delivered in a very short time. Additional chassis will be installed until the entire translation is made.

WANTED—A motor truck designer of acknowledged ability and experience, for factory now fully occupied; want an aggressive man with wide range of knowledge of the motor truck industry. Box X, this office.

The MOTOR TRUCK

Devoted to Motor Driven Business Vehicles of All Classes.

VOL. V.

PAWTUCKET, R. I., MAY, 1914

No. 5

REGULAR DELIVERY IN 100-MILE RADIUS.

How Motor Truck Economy Developed the Remarkably Efficient Service, Unequalled Facilities and Splendid Equipment of the Paine Furniture Company, Boston, Mass., Operating the Largest Store of the Kind in the World.

MAKING regular delivery by motor trucks within a radius of 100 miles of its store, and in the event of purchase of sufficient volume to justify sending them 150 miles or more away, the Paine Furniture Company, Boston, Mass., is serving its customers in practically the same manner that any enterprising concern serves a community. This statement does not mean occasional delivery, but a constant service that is as dependable as is the distribution of the locality store.

There are those who will assume that with all of the resources of highly specialized transportation companies the economy obtaining is doubtful, because of the

apparently prohibitive aspect of haulage expense, but the company has constantly increased the area in which it makes delivery and has perfected its organization until it is believed to be one of the most practical and satisfactory in the commercial world.

This statement may be regarded as broad and sweeping, but it is no more than the fact, for after long experience with motor vehicles the company has not

only practically eliminated animals, but has provided loading facilities and built a garage that will be sufficient to meet all requirements for many years. The company occupies what is claimed by it to be the largest furniture store in the world, and this was created after extremely careful analysis of business development, with every provision that experience sug-

gested. The transportation department, which is known to be fundamentally the most important of all, has been perfected to a standard that will insure the largest measure of efficiency and the greatest economy. Incidentally, the delivery equipment and facilities represent relatively a

Portion of the No. 2 Shipping Room of the Paine Furniture Company, Designed to Facilitate the Quick Handling of All Goods Shipped or Delivered to Customers.

greater expenditure than any other division.

Until April the company was established in Canal street, where its salesrooms and warehouses were in three separate buildings. Two years before plans had been developed for the centralization of all departments under one roof, and this resulted in the purchase of a property fronting in Arlington street, in the Back Bay district, extending from St. James to

Part of the Drive from St. James to Stuart Streets, 25 Feet Width. Where 30 Machines Could Be Loaded Simultaneously, to Which the Company Has Exclusive Right.

Stuart streets, on which was erected a brick and stone structure. The building has length of 272 feet and width of 100 feet, 10 stories above the basement, having a floor area of 275,000 square feet exclusive of elevators, staircases, etc., or more than six acres.

This contains the salesrooms, warehouses, shops and the factories in connection with the business, and shipping departments that will be adequate for many years to come. So spacious is the building and its departments that hundreds of people can be served simultaneously without congestion or limiting the display of stock through examination. The statement as to the magnitude of the business, the facilities for transactions, and anticipation of the needs for expansion, is made to emphasize the progressiveness of the firm.

When the company removed from the old buildings to the new store the radius of regular delivery was increased from 60 to 100 miles, not with the expectation that this might influence patronage, but because the service could be developed with a satisfactory economy and the demands of customers satisfied. The company deals at retail in medium and high quality products, and specializes the construction of exclusive designs. Its business extends throughout New England. The manufactured stock is received by water or railroad shipments and hauled from the terminals by a contractor, the company believing that this work can be done cheaper by contract than by maintaining additional equipment for work that is exceedingly variable.

While in the Canal street store the facilities for handling the stock were extremely limited. Every article delivered was taken out of a single entrance and the handling and loading was done in the street,

the goods being exposed to storms and the workers hindered by pedestrian and roadway traffic. This condition caused the annual loss of a large amount. When the site for the present store was bought, despite the fact that this afforded a street frontage of 474 feet, and that the sidewalks and roadways, little used as compared with the old store, were available, the company protected itself by purchasing a strip 25 feet wide, extending from St. James to Stuart streets, having an area of nearly 7000 square feet. At the prices commanded for Back Bay property, this represented a large investment for land that was intended, from one point of view, to be unproductive, but the intention was to have exclusive control of its loading facilities, and the cost, when weighed against the possible economy, was believed to be justified.

This strip is used for two purposes. For half the length from St. James street it was excavated and connected with the basement, this being used as an excelsior room. The room is roofed with concrete that forms a paving for half the drive. Three trucks can pass through it abreast, there is abundant space for two abreast when loaded, and 25 machines can be loaded at one time.

The No. 1 shipping room is in the basement, and the No. 2 shipping room, from which deliveries are sent out, is on the first floor. This is about 125 feet in length and 35 feet width, with six large entrances and two elevators. The entrances are protected by a wide metal and glass canopy, under which all the machines may be loaded. The shipping room is divided into sections in which are placed all orders that will make single loads, and the goods can be

Line of Trucks and Wagons Loading and Ready for Freights in the Drive at the Shipping Room Entrances, Demonstrating the Value of the Facilities.

handled without confusion. The sections are designated for different local routes and the loads are assembled by the shipping room force, so that the crews of the machines can load without delay.

The company uses six Packard trucks, three of three tons and three of two tons capacity, and besides these four horses are used, either as teams or singly, for short hauls, generally within a radius of about two miles.

Sales and Shipments.

The store is opened daily at 8:30 and is closed at 6, but during July and August it is not opened Saturdays. The shipping is without reference to sales hours. When goods are sold the samples are shown and for delivery new stock is requisitioned from the warehouses, sent to the "clean-up" room, prepared for delivering and placed in the shipping room. Occasionally several days will elapse before goods are ready for loading, although a single piece might be taken from a showroom to fill an emergency order.

When goods have been made ready for delivery great care is necessary in handling, because of the possibility of damage. With motor trucks the goods are merely wrapped to prevent marring, but the loading must be done with extreme care. Once loaded the goods may be transported hundreds of miles. Unloading must be with equal care. The satisfaction of the customer is the one object sought.

With animal delivery the haulage radius is limited to approximately 10 miles for constant work, and as this is increased additional animals are necessary, but 25 miles is regarded as the limit where horses can be economically worked, although the company often sent them greater distances. But where time was not pressing the railroads and water lines were used. Considering shipments by transportation companies, these necessitate at least six handlings, extremely careful packing, and there is no responsibility assumed by the carriers. Despite the best protection that can be given the loss from damage is considerable. When sent out by trucks and handled by men of experience the goods are generally delivered undamaged, they can be set up and arranged as desired, the house cleared and left presentable. Sometimes several hours' work will be done by a truck crew, this being a great satisfaction to a customer.

Use of Motor Trucks.

While loading and unloading is not quickly done and the time of the truck and men is not productive from the viewpoint of those who believe the machine should be constantly moving, the speed and the great-

er capacity are factors of much importance, while delivery can be made to any point at a great saving of time as compared with other forms of transportation.

The first truck bought by the company was an air-cooled machine, which was placed in service more than eight years ago. This was used for suburban delivery and long hauls, and while it was not economical as compared with machines of today, because of the inexperience of the men and the crudity of construction, the experience was such that the company believed that motor trucks could be used to decided advantage for long hauls, at least. The first truck was used for more than two years and Oct. 1, 1908, No. 36 truck, a three-ton Packard, was bought. The next truck was No. 35, which was purchased in September, 1909, and since then the other four were acquired, the last machine, No. 44, of two-ton capacity, being delivered Sept. 18, 1913. As the trucks were bought the horses used for delivery were disposed of as conditions justified, until now but four remain, and the six machines do all the work of delivery within and

How Experts Load and Protect Furniture Carried by Motor Trucks, Every Piece Being Carefully Wrapped and Roped—Why Loading and Unloading Requires Time.

without the 100-mile radius, unless, should there be emergency, the company ships by freight to local agents that will receive the goods and be responsible for delivery and setting up in precisely the same manner as are the employees that accompany the trucks.

The delivery of the goods for local and distant routes is made with much care. Assuming conditions for local distribution: The goods are taken from the warehouses and cleaned and finished. They are then placed in shipping room No. 2 in the spaces designated for the localities to which they shall be sent. They are loaded for what are known as circuits. That is, the routes are made up daily according to the deliveries and the intention is to have each driver serve a group of cities or towns, delivering in them and making collection of goods that are sent back in exchange, for repair or because of dissatisfaction. These loads are usually miscellaneous. Where full loads are carried the trips are made direct. The expectation is that

The Garage of the Paine Furniture Company in Munson Street, Boston, an Admirably Designed and Equipped Structure, with Capacity of 20 Trucks.

the drivers will take with them whatever number of helpers will be needed. The loading requires time because of the care necessary, and unloading may take several hours, as setting up and arrangement is often required. The customers are not denied this service. To the contrary, it is freely given, though it means the time of the machine as well as the men.

Long Distance Delivery.

When the loads are for longer distance a different plan is followed. Definite dates are selected for delivery in any given locality and these are posted for the information of the selling department. Thus if a Worcester customer wants to know when a purchase can be delivered the salesman can give this information, and the time allowed is such that a full load for Worcester can be sent. If the volume for any given locality necessitates an additional truck it can be provided, and the two sent together. The dates chosen depend upon the patronage, but two or even three deliveries are made weekly in such cities as Providence, and once a week or oftener Springfield, which is 90 miles distant.

Deliveries have been made as far as Lenox, Mass.; Wallingford, Conn.; York Beach, Me.; the Wallingford trip being a drive of more than 300 miles for the truck. These loads will frequently reach values of more than \$5000, and occasionally considerably in excess of that figure. With the long trips the machines are loaded the afternoon before and the start is made early in the morning, that the driver may have daylight for roads not familiar to him. With the longest drives stops are made for the night and the trip continued the second day, delivery being made and the return begun by day. The third day the trip is completed. Days when big loads and long drives are in prospect

the drivers are given short routes and later they load their machines and leave them at the garage, from which the start is made the following morning. Obviously the hours of the drivers are greatly varied, but the purpose is to equalize their work so far as is possible.

Care and Maintenance.

The drivers are developed from horse drivers, who have experience in handling furniture, and they are trained to meet the requirements of the company. Each driver is re-

sponsible for the truck and the load and the delivery of the goods, and is directly responsible to the shipper.

The trucks are kept in the garage of the company in Munson street, which is one of the finest private stations in America. The building is of brick and stone, of factory construction with a roof supported by steel trusses, and admirably lighted. The floor space, without a post, will easily store 20 trucks. The heating plant is in a basement, and over this is located a lavatory and locker room for the drivers. The repair department and the stockroom have been located, but are not yet complete, for the garage was occupied late in February and some interior fitting is yet to be done. The building is fireproof and is provided with an extinguisher system and electric light and power. There are two large entrances. In this are at present kept the pleasure cars of the president of the company and several cars owned by others, for the purpose is to store private machines so long as there is space in excess of the requirements for the company. The garage was built, however, to provide for the needs of the company for a long time to come.

The garage is in charge of a superintendent who is responsible for the condition of the machines mechanically. The plan is to have five trucks in use

Rear Section of the Interior of the Paine Garage, Showing Five of the Machines Regularly in Service Lined in Their Storage Spaces.

daily, and to have the sixth in reserve for use while any one is being adjusted or repaired or there is excess delivery. The superintendent directs all the work on the trucks, and while he is working on one the driver of the machine is his assistant. If other help is needed it is provided. In this way the drivers are trained to understand their machines mechanically, how to care for them and to protect them against abuses. The helpers are required to oil and grease the trucks, to fill the water, fuel and lubricant tanks, and the garage workers wash and clean the vehicles. The trucks leave the garage mornings in season to reach the store at 7:30, and they are generally all in by 7 in the evening, save when the long trips are made. In such work the hours are not regular. Some idea of work that can be done with the machines may be gained from the statement that directly following the holidays the company inaugurated a removal sale, and in addition to the delivery in connection with this the transfer of all the stock from the old to the new store was done by the trucks, so that the entire winter the equipment was worked to its capacity constantly.

The Matter of Economy.

The economy of the motor trucks to the company cannot be measured by comparison with animal vehicles because the machines do work that could not be accomplished with horse equipment, and results are not comparable with railroad freightage from the fact that packing, haulage at either end and damage from handling are to be added to the transportation to anything like an approximation, while the value of specialized service and attention cannot be estimated with accuracy, although it is an important factor. That the company does practically all its delivery by trucks is the best answer that can be made as to its measure of economy, and that it has established its service regularly in an area larger than most concerns serve with railroad facilities, is a sufficient indication of the results obtaining with them as against the best of modern railroad and water transportation companies.

The saving obtaining is not problematical. It has justified the creation of facilities for loading that are not equalled in America, and the construction of a garage that is sufficient for practically four times the present equipment. The investment the company has made in economizing highway haulage represents a large sum, and it has not been expended without definite knowledge of the possibilities.

The trucks are each driven from 12,000 to 15,000 miles annually and the oldest one in service is nearing the end of its sixth year, while another is well along in its fifth year. These two machines are regarded as being practically as good for the work as when they were first purchased, and in fact they are used for all the very long drives. No. 35 is the oldest Packard truck in New England, and one of the oldest in America. Basing expectation on service from the machines to date they are good for several years more, and the conclusion is inevitable that with reasonable

care and maintenance they will endure much longer than the period usually accepted for truck life. With depreciation estimated on five years the oldest truck has been completely paid for by depreciation charges earned and its service is now much cheaper, for several of the principal items of overhead have been eliminated. And the belief is that the other machines will afford equally satisfactory results.

WORLD'S TRADE OF THE UNITED STATES.

The bureau of foreign and domestic commerce of the Department of Commerce and Labor has issued a very convenient reference book for the exporter or manufacturer interested in foreign trade, entitled "Bulletin of Imports and Exports of Merchandise into and from the United States by Countries, and Principal Articles", which may be obtained from the superintendent of documents, Government Printing Office, Washington, D. C., for 15 cents a copy. The bulletin will afford to the business man instant information of the character and volume of the commerce with any foreign country, giving the quality and value of the principal purchases from the United States and the importations from that country for the years 1912 and 1913. This information was formerly included in table No. 19 of the annual report, "Commerce and Navigation of the United States", a costly and limited edition publication, but published in this form is available to practical business men at trifling cost.

WANTS WATERFRONT TERMINAL.

The Merchants' Association of New York City has appealed to Governor Glynn of that state to present to the extra session of the legislature a request that such legislation be passed as will make possible the construction of the terminal waterfront railroad proposed for Brooklyn, this to be used jointly, with equal interests in a holding company, by all railroads entering that portion of the city, and that a public hearing be held for the purpose of determining the sentiment of the business men relative to the proposition. If the railroad is constructed the belief is that it will be extremely productive of business promotion.

With liabilities of \$12,594.73 and assets of \$50,051.61, the Wambold Manufacturing Company, Milwaukee, Wis., manufacturer of brass castings, etc., has been petitioned into bankruptcy because of the inability to procure the necessary capital to meet pressing obligations.

Thomas Burneson has been appointed district manager for the Gramm Motor Truck Company, and from headquarters at York, Penn., will cover Pennsylvania and Maryland. He was formerly connected with the Kline Motor Car Company as manager of the York branch.

CENTENNIAL 'BUS MOTORIZED.

Mammoth Passenger Vehicle, in Service 40 Years, Modernized by Tractor.

The exposition that was in celebration of the centennial of the founding of the republic was the occasion for millions visiting Philadelphia, Penn., the summer of 1876, and because of the dependence on animal and railroad transportation at that time an enterprising individual conceived and constructed a passenger omnibus that was a mammoth as compared with the conventional vehicles of that time. The 'bus was several times the length of the standard vehicle and had seating capacity for 60 people, and half as many more could stand in the passage between the seats.

The 'bus was given the name "Pride of the Nation" and it was drawn by teams of 10 horses, plying between the Philadelphia City Hall and the exposition grounds. Thousands of people were transported in it during the period the exhibition was open to the public, and it was extremely productive for the owner from a financial point of view, but after the service for which it was built had ended the vehicle was sold at a sacrifice because its size prohibited its use for ordinary purposes.

It was purchased and taken to New York, where it was utilized for transporting picnic and outing parties and holiday excursionists, for its capacity of 100 persons made it extremely desirable for such occasions. For 35 years the 'bus has been used each season with reasonable profit to the owner. Despite the service it is in excellent condition and because of the possibilities through its use the owner, George Schlitz, who conducts a stable and garage, motorized it by purchasing a Knox-Martin tractor, and he is now using it with much success.

The transformation merely required the removal of the forward wheels and the attachment of the body to the turntable of the tractor, a work of trifling expense, and this done the vehicle was ready for drives

of as much as 150 miles or more a day with capacity loads. The accompanying picture shows the tractor and body with 75 persons in view on it. The proportions may be judged from the tractor and the man standing beside it. The owner is so satisfied with the 'bus as it is now equipped that he purposes sending it overland to ply between San Francisco and the Panama-Pacific Exposition, and this will probably be done at the conclusion of the present season.

WANT MOTOR RECIPROCITY.

Wherever the boundaries of the United States and Canada are separated by a waterway, especially where there is a direct line of communication, motor vehicles are driven from the one country to the other. Registration is required of the owners where they reside, but there has thus far been no recognition of foreign regulation by either country. Agitation has been begun in Michigan and Ontario, where the interests of the people are closely related, for reciprocal courtesy, so that the machines can be driven across the boundary lines, either for pleasure or for business, and it is not improbable that this will be brought to the attention of the governments officially. Local relations might be regarded, but these would not be more than courtesies, while in the event of governmental action then well defined rights could be established.

H. E. Eaton and B. G. Ward are incorporators of the Raymond Auto Wheel Company at Portland, Me., which concern is to engage in manufacturing and selling motor vehicles, wheels, etc., with capital of \$600,000.

A building at 736-40 Woodward avenue, Detroit, Mich., has been leased and is now occupied as a branch by the Willard Storage Battery Company. The branch has 10,000 square feet of floor space.

J. William Fischer, Jr., sales manager of the Silvox Company, 60 Wall street, New York City, is secretary of the Spark Plug Manufacturers' Association.

Mammoth Omnibus, Built for Service at the Centennial Exposition, Used for 35 Years in Brooklyn, N. Y., Recently Motorized with a Knox-Martin Tractor—The Faces of 75 of the 100 People on the Vehicle Are Shown in the Illustration.

WILL MANUFACTURE BENZOL.

A plant is to be constructed at Farrell, Penn., by the United States Steel Corporation at a cost of about \$400,000 in connection with the coke ovens operated at that place, for the manufacture of benzol, and it is expected that the plant will be operating in approximately a year. The purpose is to produce benzol, which has a very satisfactory efficiency as a hydrocarbon fuel, in large quantities, and to sell it for general use in internal combustion engines of all kinds.

The company has produced benzol in small quantities and after the fuel had been tested in differing uses decision was reached that it could be manufactured wherever the coke ovens are located in sufficient quantity to warrant it being taken up as a practical commercial product. Benzol has been used to considerable extent in Europe and while the possibilities for production are limited it has much to recommend it, having greater fuel value than either alcohol or gasoline. One advantage is that it may be used with any form of carburetor constructed for use with gasoline. If the plant is a success it is not improbable that others will be built wherever the company has coke ovens. These are now located at Sharon, Penn., Gary, Ind., Joliet, Ill., and Birmingham, Ala.

RUTHERFORD PROMOTED.

W. O. Rutherford, who was for four years assistant to H. E. Raymond, second vice president and general sales manager of the B. F. Goodrich Company, Akron, O., has been made assistant general manager for the company and the scope of his duties has been considerably extended.

The address of the United States Light & Heating Company's general offices will be at Niagara Falls, N. Y., after May 20, at which date they will be established at the factory. This change will enable the company to consolidate the administration, sales, engineering and production departments.

QUICK LUMBER HANDLING

Combination of Loading Crates and Platform Truck Minimizes Yard Labor.

The Hawkeye Lumber & Coal Company, Cedar Rapids, Ia., one of the largest concerns in that city, does an extensive lumber business, deliveries being made for considerable distances outside of the municipality. For years haulage was by animals and the experience with these was practically the same as those using them for highway transportation. The company purchased a two-ton B. A. Gramm's truck for use on the longer hauls, or where it could be advantageously utilized.

The purpose was to keep the machine moving as much of the time as was possible, and experience soon demonstrated that with the best yardmen working but little gain could be made in loading, while unloading was quite as slow a process, for only the driver might be available to do this work. As an experiment a number of crates were built, these consisting of a stout platform with stanchions or stakes at either side. These were placed on yard hand trucks and loaded in the yard or lumber sheds, the trucks being eventually placed on loading platforms so that the decks of the hand and motor trucks were about the same level.

The motor truck is backed to a loading platform and the hand truck moved as close to it as is practical. The platform of the crate is dropped on to a roll set slightly above the deck of the motor truck. By turning the roll with a hand crank the crate is drawn on to the motor truck, other rolls taking the load as it advances, one man in this manner moving the load quickly and without hard labor. When the load and the crate is on the motor truck it is secured with a binding chain or rope and can be carried wherever desired. At the destination the load is unbound, and by reversing the movement of the rolls the load is dropped easily to the ground. The crate is picked up at convenience or when the next load is delivered.

Handling Lumber with Loading Crates, an Equipment Used by the Hawkeye Lumber & Coal Company, Cedar Rapids, Ia.: At Left, the Loaded Load on a Hand Truck Ready for Transferring to the Machine; at Right, the Crate Transferred by One Man with Great Rapidity.

The loading of the crates is done by the yardmen without reference to the work of the machine, there being a sufficient number so that there is no need of waiting for those sent out with deliveries, and work can be planned very systematically. The company uses the crates for lumber in length, such as is shown in the accompanying illustrations, but also for shingles, sash, doors, blinds and other materials in bundles. The pictures show the truck with the load ready for it on the hand truck, and again with the load ready for haulage and the hand truck cleared for another crate and load. This method of handling has been found to be very economical of the time of the men and the machine, and the cost of equipment is not only trifling, but when once procured will serve for a long period of time.

TRUCKS FOR COTTON HAULAGE.

Haulage of cotton is extremely important in many of the southern ports, where the bales are brought to tidewater or to the terminals by rail, and thence shipped by steamer or vessel to northern coast points for transshipment to the manufacturers. The necessity of handling the cotton economically and quickly has been the occasion of considerable experimental work with motor trucks, especially in Galveston, Tex., where several GMC electric machines have been fitted with special bodies. Because the bales are bulky and handling should be minimized, considerable attention has been directed toward the construction of what will afford ample body space and quick loading and unloading. After numerous experiments, what is believed will be a satisfactory type has been produced, and several trucks with these bodies are now in use. If they are found as practical after use for a sufficient period as they are believed to be a considerable number will be similarly equipped.

TRUCK PARADE FOR MILWAUKEE.

Plans are now making for a big parade of motor wagons and trucks that has been organized by the Milwaukee, Wis., Automobile Club, the purpose being to invite all owners in that city and vicinity to make a demonstration that will create interest and impress upon the people generally the number and the utility of the machines now in service. The event will be one of the features of the observance of Memorial Day.

C. J. T. McCaffry and E. C. Reed of Washington, D. C., and C. C. Guyer of Wilmington, Del., have organized the American Auto Tractor Company with capital of \$300,000, to build motor vehicles, engines, tractors, etc.

George V. Lyons has been appointed manager of the San Francisco branch of the Moreland Motor Truck Company.

AUSTRALIAN MOTOR IMPORTS.

The value of the motor vehicles of all kinds imported into New South Wales in 1913 was \$2,789,159, which, compared with the importation of machines valued at \$2,873,696 in 1912, shows a shrinkage of \$84,537 for the year, but the value of the imports from the United States during 1913 was \$646,038, which was a gain of \$93,344 over 1912, when the value was \$552,674.

The 1913 imports were made up of \$2,205,317 for chassis, which shows a loss of \$110,597 when compared with the chassis imports for 1912, but there was a gain of \$24,225 in body valuations and of \$1835 in motorcycles, the 1913 totals for the two being \$376,238 and \$207,604 respectively. The imports from the United Kingdom totalled \$768,415 in 1913, this being \$28,297 less than in 1912, but the imports from the United States increased. France was third in the list with a total of \$233,694 for 1913, this showing a loss of \$88,458; Canada was fourth with \$214,443, a gain of \$52,481; Germany was fifth with \$144,267, a gain of \$11,559; Italy was sixth with \$139,566, a loss of \$69,241; Belgium was seventh with \$47,801, a loss of \$80,393; Switzerland was eighth with \$3844, a loss of \$1631; Sweden was ninth with \$3451, a loss of \$19,932; Netherlands was 10th with \$2142, a gain of \$1251, and Austria was 11th with \$1654, a loss of \$11,320.

GOODYEAR ABANDONS RETAIL SALES.

The sale of Goodyear tires was on April 1 placed in the hands of retail dealers throughout the country, and the products of the Goodyear Tire & Rubber Company, Akron, O., are now being distributed from the 60 different branches and service stations. This policy is expected to work out very satisfactorily, as it will not bring the company and the retailers into competition. The result will undoubtedly mean the relocation of some of the branches, which will be more of the nature of warehouses, and where practical these will be established in connection with the series of service stations that the company had opened in a considerable number of the larger cities.

CREDITORS GET BIG DIVIDEND.

A dividend of 40 per cent. has been received by the 58 creditors of the B. F. Board Motor Truck Company, Washington, D. C., which was declared bankrupt July 9, 1913, by the distribution among them of \$9463.79, and it is believed that a dividend of perhaps 30 per cent. more will be paid.

The Ferro Machine & Foundry Company, Detroit, Mich., has appointed Roland Cole, formerly connected with the Yawman & Erbe Manufacturing Company, Rochester, N. Y., its advertising manager.

ASPHALT PAVING HAULAGE.

Fleet of Nine White Trucks Bought by Brooklyn, N. Y., Construction Firm.

One of the problems of contractors for street construction, where the paving is asphalt, is to have the material in condition for application when delivered at the job, for with rare exceptions conditions do not permit or justify the establishment of a temporary plant. Asphalt as a material may be received in drums or barrels or other containers, but when applied it must be mixed with sand or gravel to give it sufficient body, for the asphalt will soften at comparatively low temperature and will be cut by the wheels of the traffic over it. To minimize repairs and attention the asphalt is prepared by heating and mixing, and this can only be done where there are facilities adequate for the work, for obviously the materials must be in quantity, the sand or gravel must be dried or heated, and the asphalt must be liquefied so that it will penetrate the sand thoroughly.

If permitted to cool the mixture cannot be worked, and when solidified it must be broken and heated, necessitating expensive work. It can only be applied to dry surfaces, and usually it is spread by rakes and then rolled to a uniform thickness. Generally the contractors prepare the mixture at a permanent plant and depend upon carrying it heated to the job. If the haul is long there is probability of cooling, and in any event it will be difficult to handle because of adhesion to the vehicle in which it is transported.

Handling asphalt in motor trucks requires a body that can be elevated to such a degree that the load can be dumped by gravity, for excessive heating will destroy the asphalt, as it will become hard and will crumble when cold. Quick handling is the solution of the work and such equipment as will make possible the elevation of the body sufficiently to a point where the load will discharge. To meet the requirements of its work the Brooklyn, N. Y., Alcatraz Asphalt Company recently purchased nine five-ton White trucks, fitted with steel bodies and a power hoist by which the highest elevation can be reached in 30 seconds. These machines are now in service in New York City and have given the fullest degree of satisfaction. This is the largest number of motor trucks operated by an asphalt construction company in America and probably is not equalled in the world. With these the operations of the company can be extended very generally and a superior quality of work done at distances.

"RAISE RATES" SAYS WILLYS.

Big Motor Vehicle Manufacturer Advocates Advance Asked by Railroads.

John N. Willys, president of the Willys-Overland Company, executive of several other concerns of prominence, and second largest manufacturer of automobiles and motor trucks in the world, has declared himself squarely as favorable to the increase of railroad freight rates for which authorization is sought from the Interstate Commerce Commission, this being in striking contrast to several automobile manufacturers who have strenuously objected to any change from the present charges.

Mr. Willys did not make this declaration without careful consideration, and it was then in the form of a communication to the Interstate Commerce Commission, which was substantially as follows:

After considering from every angle the matter now before your honorable body, pertaining to the general increase in

White Five-Ton Truck Chassis Fitted with Special Power Dumping Body, One of a Fleet of Nine Purchased by the Brooklyn, N. Y., Alcatraz Asphalt Company.

rates, I am constrained to write and express to you my belief in the advisability of such action. I am convinced that conditions warrant it and that carriers are entitled to a larger revenue for the service they perform.

So I would respectfully ask to be placed on record as not only not objecting to the increase, but as strictly advocating it, notwithstanding the fact that it will mean a large increase in the expenses of my company.

I might add that the Willys-Overland company and the several companies owned by it and myself, making parts for Overland cars, are, as you are doubtless aware, heavy shippers. The Willys-Overland company alone ships and receives approximately 16,000 carloads per annum and pays freight charges on inbound carload shipments, exclusive of coal, oil and lumber, considerably over \$200,000 per annum.

J. G. Buchanan, M. H. England and A. Black are the incorporators of the Pittsburg Model Engine Company at Pittsburg, Penn., with capital of \$750,000, to manufacture and sell gasoline engines for motor vehicles.

To engage in the manufacture of carburetors, etc., the Ahlberg Kerosene Carburetor Company has been incorporated at Pittsburg, Penn., with capital of \$300,000 by M. J. Dain, H. Davis and P. W. Burke.

UNIVERSAL TRUCK ACCOUNTING SYSTEM.

Simplified Record of Work and Operating Expense and Revenue for Motor Vehicle Service Adaptable to Any House Bookkeeping and Any Equipment in Use.

(Copyright, 1914, by The Automobile Journal Publishing Company—All Rights of Use or Publication in Any Form Reserved.)

PRACTICAL accounting of transportation department expense and revenue has been advocated by thousands. The necessity of accurate determination of operating cost and earnings is admitted by all who have to do with motor vehicles—those identified with the industry, with the sale of machines, with their use and maintenance, and those who are studying the economies obtaining from their service. The value of actual data is understood, but as they can only be obtained with experience, and there are innumerable variables that have material bearing on results, only where a motorized equipment has been used for a considerable time are dependable figures obtainable.

The adoption of a system that might be productive of accurate facts is seldom seriously considered, because where a house method of accounting has been the vogue any variance from this would result in confusion or, perhaps, a complication, and simplification of accounts is absolutely essential. The business man will hesitate if accounting of a transportation department will necessitate a radical change in his office work, or will add materially to it. While he will admit the need, the system that will appeal to him will be that which will supplement what he already has in use, and he will reject that which will not coincide with it.

Not only this, business men are not agreed as to the factors that should be incorporated in a system. Believing that these are all variables, and that what might be applicable to the

TOR TRUCK has had developed a system that is intensely practical, that is equally as well adapted for the largest transportation department as for the business that uses a single vehicle, that can be adopted at any time without change of bookkeeping methods, and covers every detail with absolute accuracy.

The Universal Truck Accounting System.

This has been given the title of Universal Truck Accounting System. It has been copyrighted and application has been made for the registration of this title as a trade mark in the United States patent office, that there shall be exclusive right to this title and to the system as devised.

The system consists of a series of forms, but three of which are active. One of these is a card showing the detail of the day's work, operating expense and earnings and an accident report; all the others are contained in book form and include the record of investment, the constants of the fixed charges, the monthly record by days, the cost and service of tires, and an illustration of a method for obtaining a statement of productiveness and present value of any vehicle for any given period. These records afford every detail of estimated and actual operating expense, revenue from service, revenue from other sources, gross and net earnings, mileage driven with and without load, the weight of loads carried, tire cost, etc. From these at any time the actual value of the machine and the

DETAIL RECORD OF VEHICLE SHOWING CHARACTER AND VALUE OF INVESTMENT.

Office Truck No.	Make	Motor Number	Capacity	Weight	Date Purchased	Date Delivered	Chassis Cost	Body Cost	Accessory Cost	Total Cost	TIRE EQUIPMENT	
											Front	Rear

This Form is the First of Three Printed on the Second Cover of the Daily Record Book and is to Be Filled When the System is Inaugurated—Size of Form, 13.5 Inches Width and 1.25 Inches Depth.

one business might not yield satisfactory results with another, they are inclined to doubt the practicability of adopting them. Besides, varying uses afford differing aspects, and what might be with one a factor of importance may be of little or no consequence with another.

Audit Only Guide Series of Accurate Constants.

The real determination of operating cost of a business can only logically be obtained by an audit of the books, and an analysis of facts and conditions, which may be assumed as unnecessary or undesirable from the fact that auditing would only yield a series of constants with which comparison of future expense might be made to determine possibilities for economies.

Records as proposed or suggested have appeared to be too detailed, or apparently required too much clerical work without sufficient return for the additional labor and expense, or they have obviously been insufficient. Those having but one or several machines believed that reasonably accurate figures were obtainable from the records kept, and those with considerable numbers, seeking dependable information, found even complicated systems unproductive of satisfactory data.

Confusion of Factors for Accounting.

The MOTOR TRUCK'S writers investigating highway transportation have found that with rare exceptions records kept are either insufficient or incomplete, that they seldom if ever include all factors of importance, that there is decided confusion of the factors generally used, and surprising variance of opinion relative to methods.

To supply a need that exists with a majority of those using motor vehicles, to make possible the accurate accounting of expense and revenue from power wagon equipment, the MO-

value of its service, its earnings, the profit or loss, and every item of expense of operation or revenue can be determined for any given period, as well as the average for the week, month or year.

Simplicity and Accuracy Are Features.

The system has been worked out with a view of providing for every detail, and of being extremely simple. Extreme care has been taken to insure accuracy. Complications have been avoided, and yet the records are so comprehensive that there is at all times check against any particular entry, and there is no possibility of an error. There is no reason to refer to other records, such as ledger accounts, in which will be carried some of the charges, but these will be general rather than specific and will include totals rather than items.

The scope of this system will be outlined and the specific uses of the record described in detail. First the use will be applied to a new vehicle, and following this will be given an example of utilizing it with a machine that has been in service for a period.

Operating Detail Fully Recorded.

The purpose is to have an absolutely definite record of every use made of the vehicle, and to credit it with every mile it is driven, with every weight carried, with whatever service is performed, and the time that it is on the road. It is credited with every earning, and against it is charged all costs, fixed and variable, with provision for determining the value of the variables whenever this is necessary. For the purpose of convenience the daily record is made in card form, but each day's record is transferred by totals into a book containing 12 sheets, each of which is a monthly record when footed. From this the daily averages are computed. Beginning with a new machine the constants are entered on a form on the inner

CONSTANTS OF THE FIXED CHARGES SHOWN BY ANNUAL AND DAILY COST.

	INSURANCE				TRUCK DEPRECIATION		STORAGE		INTEREST		TAXES		Est. Daily Operating Cost	Tire Operation Mileage Cost
	Fire	Liability	Property	Total	Annual Cost	Daily Cost	Monthly Cost	Daily Cost	Annual Cost	Daily Cost	Annual Cost	Daily Cost

This is the Second Form Printed on the Second Cover of the Daily Record Book and is Filled When the Accounting is Begun—Size of Form, 14.75 Inches Width and 1.625 Inches Depth.

cover, and with a statement of fact concerning the machine. At the same time on the tire record is entered the detail of the tire equipment, and to this is added whatever may be necessary as renewals or changes are made. Thus the first entries are made on the cover of the book, which is an office record, and on the tire card.

Fixed Charges Carefully Apportioned.

The data, so far as the fixed charges are concerned, are averaged on a basis of a given number of working days annually, the cost being shown by the day and by the year, save for the item of storage, which is expressed as monthly and daily cost. Thus interest, taxes and insurance are stated in annual totals, divided by the number of working days, and the garaging by the monthly charge, divided into a definite daily expense. The item of depreciation is not shown as an expense. Depreciation is based on an estimated period of service of the machine and the cost is divided into annual divisions of 12 months, so that the annual depreciation is averaged to be a specific amount daily.

Valuation of Work Done by Machines.

Whatever the work done, this must be based on the operating cost of the machine, which is estimated as a reasonable amount. Then, if the truck is used for route delivery, for instance, a value must be placed on the truck's service. By this is meant that as there is no payment made by customers for its work it cannot be credited with a precise revenue, but to do this work would cost a certain amount, and the truck's work is worth the amount this work would cost by other vehicles giving similar satisfaction. To illustrate, if the machine is doing delivery that would cost by contract or other vehicles a given sum, the value can be set at that figure.

The reason for valuing the truck's service is that, unless it can do work that has value, it is a poor investment. It must do a given work to be a good investment and that work is measured by dollars and cents. The cost of doing the work is estimated. This is stated as a basis for comparison. The expectation is that the work can be done for less than the estimated price and the purpose of accounting is to minimize the cost. If the vehicle can do more work its value is increased, and this must be represented by additional value in route work. The service that is paid for will show revenue, against which is charged the expense of operation.

In the event that the machine has been used for a period the constants are entered as with a new vehicle, but the depreciation is based on the lessened depreciation period.

Daily Report Card Shows Complete Record.

The daily record is a card 16 by 13.75 inches, perforated so that when folded it is 13.75 inches length and eight inches width. This is printed in black on a flexible manila stock and is carried in a substantial cover that fully protects it. The left half of this card is defined as the Motor Truck Daily Report. The right half is the Motor Truck Daily Operating Cost. One card is given each day to a driver and on this on the left side is entered the date, the owner's number or designation of the vehicle. These entries and the Office Instructions to Driver are filled in the office so far as this is possible. The remaining entries of the driver's instruction blanks are filled by the driver.

Reading from the top of the card the first entry is the condition of the machine, which is noted previous to the start. The weather conditions are similarly noted at the time of leaving, and under the heading of Drivers' Working Time the time of leaving the garage is entered, as well as the driver's name. The

[illegible]

This Form Is on Sheets 23 Inches Width and 12 Inches Length, 12 Being Bound with Two Tire Records, the Book Containing Complete Details of a Machine for One Year When All Entries Have Been Filled—The Sheets Are Bound with Stout Manila Card and Are Well Protected.

speedometer reading before the start is taken by the driver.

The driver then follows the instructions noted in the blanks, four separate entries being provided on each card. If the work is on a regular route the number or designation of the work is indicated. If the machine is to make a trip, if it is rented, or if it is a job, the work is shown, the job being entered by number or title. Then follows in sequence the name of the customer, the name of the individual to whom the driver shall report, the address of the person, the time to report, and the destination, if this shall be known; the name and the address to whom delivery shall be made may be supplied after reporting, but the time of delivery and by whom the delivery was received are entered at the destination.

On the return the driver enters the time and the mileage of the trip, the number of miles driven loaded, the number of miles driven unloaded, the time delayed, the cause of delay, the actual driving time. When the load was placed on the machine the driver enters the number of packages (if a route or a special distribution of small units), bales, barrels, cases or miscellaneous, the last mentioned classification showing the character of a bulk load as of furniture, lumber, or any similar freight that cannot be better specified, with the estimated or known weight of the load. If the office desires to have the driver collect the payment for the work the amount is entered and he is instructed to make collection. If the work is charged this is also indicated. In the instruction is every detail that might be useful in making a price for a work that was unknown to the office aside from receiving an order for a machine to do a service. In the event of trips of comparatively short length the blank will provide for four, and should there be route work the driver can be given specific instruction with reference to four deliveries on one or as many different routes.

During the day the driver is required to note the time storms begin and cease and the general road conditions, at least so far as these would affect his work, there being space for recording several. For instance, following the notation "Storm Began" entries of 10:15 and 4:21, and an entry of 12:55 following the notation "Storm Ceased", would indicate that the storm of the morning continued from 10:15 to 12:55, and a second storm began later in the afternoon, the driver entering rain or snow as necessary, and with whatever will show the driving conditions. The speedometer reading at the end of the day is noted, as well as the total, with the total number of miles driven loaded and miles driven light, the time of returning to the garage, the total hours the machine was out, the total hours worked and the number of hours of overtime. Before the driver leaves the garage he enters the condition of the machine—if repairs or attention are necessary, these are

Record of Repairs and Accidents.

In the event of adjustments or repairs being made on the machine, these are specified in detail and the name of the person authorizing the work is stated. If the work ordered by the owner or driver is completed this is noted, and if not completed the reason is stated. When inspection of a machine is ordered and work is found necessary the requirements are stated on the card.

Should there be an accident the driver is required to note the time and to specify whether personal injury or damage to property or to the machine has resulted. On the reverse of the card is an accident report, in which is entered the date, the time, place, the damage to the vehicle, damage to the load, the name and address of the owner of the load, with a blank for entering the cost of adjusting the load damage; the name of a person injured with address, and the names and addresses of three witnesses. The exact detail of the accident must necessarily be made in the form of a report to the insurance companies. In connection with this report is a blank for entering the items of machine repair, specifying mechanical work, painting and tires, directly resultant from the accident.

The Daily Record in Daily, Monthly and Annual Form.

The book record consists of 12 sheets bound in a substantial cover. This is to contain the summary from the Drivers' and the Daily Operating Cost card, each line showing the complete totals for the day. First is entered the name of the driver, and then in sequence the amount of the wage of the driver, the wages of the helpers, the cost for gasoline, electric current, oil, grease and miscellaneous expenses; the cost of repairs resulting from regular service and from accident; the items for daily overhead expense, including interest, taxes, insurance and storage; the total daily mileage and the miles driven loaded and light; the record of each tire, showing the number, the mileage and the repair cost, with provision for two changes, and the cost and repair of tubes; the total operating cost and the total earnings. At the expiration of the month the sheet is totalled. Assuming an instance: From a previous sheet a total for say three months is brought forward, and the figures for the month and the three months totalled, this sheet then giving the figures for each day of the month and the total for the four months. The daily average for the month is entered under each footing, under this the daily average for the three months, and then the daily average for the four months. This can be applied for any number of months, from two to 12, and will give absolutely accurate figures, so that it is possible to make comparison at the end of any period to ascertain precise results, with reference to any desired detail. It is also practical to compare days or weeks or any term that may be necessary.

Constants Used in Operating Record.

On the inside of the first cover are two forms to be filled with record data and the constants to be used in filling daily work and cost card. The first includes the office number of the machine, the make, the motor number, the capacity, the weight, the date bought, the date delivered, the chassis cost, the body cost, the accessory cost, the total cost, and the size and cost of the tire equipment. The second is for entering the fixed charges. The insurance is differentiated as fire, liability and property; the date each policy is effective, the dates of expiration, the annual and the daily cost of each form of policy is specified, and the total of the annual and daily cost is shown. Under depreciation is indicated the annual charge and the daily cost, the former being on a basis of a definite life of the machine, and the latter on the annual charge divided by the estimated number of working days. The charge for storage is given by the month and the day, because of the possibility of a change in conditions during a year. The interest and taxes are entered as the annual costs and daily costs, each total expenditure being divided by the number of working days. The estimate of the daily operating cost is stated, this being comparable with the actual figures shown on the sheets.

The Complete Record of Tire Cost and Service.

With each book, which is designed for the records of a single machine for a year, are two tire record sheets, each having space for 30 different entries. These are carried across the page, and are in sequence for the tire number, the type, the make, the size, the maker's number, the cost, the date bought, the date put on, the date taken off, the mileage driven, the mileage guarantee, the mileage less or in excess of the guarantee, the cost of repairs, the salvage, the adjustment obtained, the estimated cost a mile (based on guarantee), the actual cost a mile, the loss and gain (the difference between guaranteed mileage cost and the actual cost), and the amount to be charged or credited to or against the truck at the expiration of the service of the tire.

Formula for Finding Operating Cost and Earnings.

On the inside front cover is shown a method of determining at any time the value of the machine, its operating cost and earnings, by the record contained in the book. The original cost of the chassis is debited, and against this is charged the amount of depreciation, ascertained by multiplying the daily charge by the number of days worked. As this depreciation has been earned by the truck the actual cost is the chassis price less the depreciation earned. Thus, if the chassis cost was \$3000 and the depreciation earned was \$600, the net cost would be \$2400. This depreciation may be credited to a depreciation account or turned into the general revenue of the owner. In any event it is credited against the chassis cost, and as this depreciation has been earned it is either avail-

able as a special fund which accumulates until it equals the price of the machine, or it is turned into general earnings, from which eventually replacement shall be made. Depreciation as found will make possible a statement showing the cost to a day for the owner's service. But depreciation must not be confounded with an estimated market value, for while a machine might be worth its full cost to the owner for a stated work, it might not sell for a half that amount when offered in the market. However, should there be a desire to determine the shrinkage of the value, this can be ascertained in the instance illustrated, by deducting the market price estimated from the actual cost, which was really \$2400 instead of \$3000. As a matter of fact, if the machine be well maintained, the shrinkage will be comparatively small. If it should be badly damaged, as by an accident, the shrinkage would be relatively much larger. Such loss could not be regarded as normal depreciation, and could not be anticipated. If the truck has been used rationally and is in good condition it may be worth the full cost to the owner, or as much as a new machine for his purpose.

Tire Depreciation Not Included with Chassis.

As the tire cost is kept separate from the chassis and each renewal means full restoration, depreciation is not figured on them. Taking the market price of the tires and the service guarantee as two factors the cost a mile can be accurately learned. The unused mileage must be regarded as worth the value guaranteed. Then the value of the chassis and the remainder of the guarantee gives the valuation of the machine and the tires. The difference between the total revenue from operation and the total operating cost gives the net earnings. Shrinkage in chassis value, a real operating charge,

METHOD FOR FINDING TRUCK VALUE AND EARNINGS.

STATEMENT OF TRUCK OPERATING COSTS AND EARNINGS.			
Total Operating Cost	\$2500	Total Revenue	\$3000
Net Earnings	500		
	\$500		
STATEMENT OF PRESENT VALUE OF TRUCK.			
Investment - Less Tires	\$3000	Depreciation Earned	\$ 600
		Actual Cost of Truck	2400

The Above Form Is Printed on the Second Cover of the Book and as Filled It Shows the Factors and Method of Reaching a Precise Statement Whenever Desired.

can be included in the cost of operation, and the net earnings correspondingly reduced, but shrinkage is a factor that can only be determined by the owner's judgment.

The explanation of this system has required much space because so many details have been provided for, but examination of the forms will show that its simplicity is remarkable, and that every fact of value is accurately kept. Nothing is approximated, nothing is uncertain, and at any time a satisfactory balance of the account of a given machine can be found.

NEW M. A. M. MEMBERS.

The membership of the Motor & Accessory Manufacturers has been increased by the admission of the following firms: English & Mersick Company, New Haven, Conn.; Van Sicklen Company, Aurora, Ill.; Forbes Varnish Company, Cleveland, O.; Detroit Pressed Steel Company, Detroit, Mich.; A. O. Smith Company, Milwaukee, Wis.; T. P. Powers, Newark, N. J.; Perfection Spring Company, Cleveland, O., and Pittsburg Steel Products Company, Pittsburg, Penn.

HIGHWAY HAULAGE CONGESTS RAILROADS.

Splendid Organizations Made Inefficient by Absence of System Outside of Terminals---Consolidation of Transportation Interests and Co-Operation the Remedy.

THE conclusion that a great deal, if not all, of the congestion at railroad and general shipping terminals was due to the present inefficient and extremely expensive methods of highway freight transportation, and that improvement could be made by method and organization of those who now perform service without regard to system, may be stated as a summary of the address made by Fred A. Hortter, car accountant of the Boston & Maine railroad system, made before the Electric Vehicle Association of America at its meeting in New York City April 24.

This may be regarded as the first carefully studied statement coming from a man identified with a railroad of large proportions, and Mr. Hortter's particular duties have made necessary constant observation of conditions with reference to receiving and delivering freight at terminals. The railroads have organizations created to perform specific work and each co-operates with the other. The results depend entirely upon system. In contrast with this the haulage of the freight to and from the terminals is governed by the conditions obtaining with the contractors or the consignees, the work being done without anything else than convenience being considered.

In other words, the railroads have organizations, trained men and constant supervision. The public carries the freight to and from the stations, without organization. Were the railroads and the public to co-operate there would be material improvement. As it is the efficiency of the railroads is lessened by the absence of co-operation. The inference from Mr. Hortter's paper is that the improvement of conditions, so far as the freight houses are concerned, must necessarily come from without, and as these are improved the service for the public will be materially bettered.

Mr. Hortter did not go into detail as to how remedies might be made, but he made himself perfectly clear that consolidation of highway freight transportation service would lead to material betterment, and undoubtedly large economy, and would facilitate delivery to a degree little realized. The address follows:

Mr. Hortter's Address.

The latest available Interstate Commerce Commission report on railroad freight service, covering the year ending June 30, 1911, showed a freight equipment of slightly over 2,195,000 cars, and a freight movement of nearly 254,000,000,000 ton-miles. That the growth of this vast business has been as rapid as the development of the country is evident to everyone here, and, while many of you gentlemen are not directly connected with railroading nor familiar with its practices, you can readily imagine the problems involved in the efficient administration of this vast enterprise.

Although the major problem with which we are to deal tonight and upon which this paper directly bears, is that of terminal freight congestion, it is pertinent that a resume of the methods employed in this freight movement be here introduced as indicative of the effort and study devoted by the railroads to the economical conduct of their business, and of the

manner of solution of the problems, which in themselves are distinctly those of operation and directly connected with the railroad properties.

In considering the methods under which the railroad freight transportation of the country is accomplished we will disregard that portion which is not handled directly through freight terminals such for instance, as is loaded and unloaded at private sidings.

Classification of Freight.

For the purpose of general classification, freight may be divided into two principal classes, designated as "Carload" or "C. L." freight, and "Less-than-carload" or "L. C. L." freight. As a rule, the terminal rate for the delivery of merchandise implies the delivery to the consignee at the local freight yard terminating the trunk line on which the tonnage enters, from which point the goods are teamed to the premises of the consignee. It is customary for the shippers and consignees to handle carload freight directly into and from the freight cars, and to handle less-than-carload freight through the freight houses, unless other methods are specifically requested by consignee. The loading of freight cars to their full capacity is constantly made the subject of supervision by the railroads, with the inevitable consequence that the average tons of freight handled per car have steadily increased.

Every effort is made to assemble L. C. L. freight for one destination in one car, or if this is inadvisable because of the small volume, freight for several stations near together is loaded into one car, thus permitting a through haul on the road and eliminating unnecessary handling of cars or freight, the loading being systematized so that the car may reach its farthest point in the direction of its final destination before contents are handled.

In the same manner the carload minima have been regulated as far as possible so as to provide for utilizing the utmost carrying capacity of the car, in the case of full carload shipments which are loaded by shipper and unloaded by consignee.

Handling by Railroads.

When cars are loaded and ready to move, they are assembled in trains on classification tracks. In order to group as many cars as possible going in the same direction to or via a common point. This eliminates switching in transit with its attendant delays. As study and experience, or variation in operating conditions indicate a necessity for a change in the methods, corresponding modifications or amendments are made, always with the view of efficiency of operation.

The operating superintendents and the forces reporting to them are daily confronted with constant changes in the volume of freight to be moved and the necessity for the utmost economy and efficiency in handling it. The transportation department of a railroad is therefore continually compelled to study these changing conditions, and through supervision by the superintendents and their subordinates, any lack of economy or want of efficiency is quickly discovered and defects rectified.

As a slight indication of what this means, it may be of interest to outline briefly the amount of freight that is handled by only one railroad in one city, this road operating approximately 50 inward and 50 outward freight trains each day. During the week of Oct. 16, 1913, this road handled through its freight houses and team tracks a total of nearly 110,000 tons of freight, being divided approximately into 60,000 tons inward and 50,000 tons outward. Were it possible to team this freight at what you electrical gentlemen term a "high load factor", its movement would be greatly simplified; but observations show the "peaks" of this service to occur in the early morning and late afternoon hours, so that in from six to seven hours of the working day less than 35 per cent. of the total yard traffic movement occurs. The elimination of these "peaks" is one of the problems of the railroad terminal question.

Demurrage and Its Charges.

Another problem of freight terminal operation, with which the railroads are confronted is the continuance of a practice of 25 years ago, where shippers and consignees use the railroad premises for storage purposes. The extent of this abuse of railroad facilities led to the formation of car service and car storage associations, sometimes designated as car demurrage bureaus. Under the operation of these bureaus consignees and shippers were penalized for using the railroad facilities for this purpose beyond a certain designated free time. These associations grew up in various parts of the country until practically the entire territory was covered. The railroads delegated to them the handling of these demurrage charges or penalties, thereby eliminating any question as to favoritism in assessing demurrage and storage charges that would result from competitive conditions. The free time varied from 24 to 240 hours, according to the purpose for which the free time had been allowed and the conditions under which freight was detained.

It had always been evident that considerable advantage would result to all the business interests of the country as well

as to the railroads, if uniform car detention rules could be adopted everywhere. Consequently, in 1908, a committee of the National Association of Railroad Commissioners, in conjunction with a committee of the Interstate Commerce Commission, made a thorough investigation of this subject of car demurrage, and recommended a set of rules which were adopted by the association and indorsed by the Interstate Commerce Commission. These rules, known as the national code of demurrage rules, have since been almost universally adopted by the different states.

The advantages of uniform car demurrage rules made it very evident to the American Railway Association that uniform freight house storage rules should, if possible, be adopted, and during the last few years a standard code of freight car storage rules has been formulated and recommended for adoption by the American Railway Association.

Of course the purpose of these charges is to force the removal of freight by penalizing those who leave it for an unreasonable time on the railroad premises. Logically the demurrage should be high enough to insure this result without undue burden to any who may happen, by reasonable exercise of unloading facilities, to be unable to remove the freight within the free time. To accomplish this the free time allowance in one section of the country varies considerably from that of another, depending upon the nature of the freight and of the facilities for handling.

Study of Short Haul Methods.

All of the foregoing is indicative of the serious attention and study which have been given to the improvement of conditions involved in the so-called "long haul" of freight from city to city; but it is only recently that the necessity for giving an equal amount of study to the so-called "short haul", or teaming of freight from terminals, has been impressed upon the transportation interests.

Investigation has resulted simply in emphasizing the defects of the systems employed, but whatever remedies have been suggested have mostly emanated from and been put into practice by the railroads themselves. These improvements have generally been to little purpose through the lack of co-operation between the carrier and the public, and the inability of the railroads to control the operations of the teamsters and truck men.

This brings us directly to the main cause of railroad freight terminal congestion, namely, the present methods of highway freight transportation. The practices in vogue in this service have not radically changed during the last generation, while the conditions of operation have continually grown more complex through the increase in volume of freight handled.

From my office window I look out upon one of the principal avenues leading from the business district of Boston to the freight yards of the Boston & Maine railroad. From my observation of the traffic on this highway, it has been evident to me for many years that the movement of freight through our city streets has been conducted with very little effort to systematize the handling of the different lots of freight in an efficient and economical manner.

Lack of Efficiency Apparent.

To substantiate this let me cite one or two instances which have come to my notice which also show with what the railroad must contend in its effort to comply with the demand for efficient service. Observation of the terminal yard teaming in the Boston & Maine railroad yards in Boston showed that in one day 10,264 horse drawn vehicles handled freight to the out-bound freight houses. The total outward tonnage for the week amounted to but 22,416 tons, which showed an average horse vehicle load of only .36 of a ton each. Calculate for yourselves the efficiency of a five-ton unit operating under this load factor.

In another observation in a trucking concern hauling approximately 180,000 tons of merchandise annually, the ratio of loaded and empty mileage of the horse vehicles was found to be 241:143, while the actual moving time represented but 22.95 per cent. of the total day's work.

Of course these figures show the actual conditions studied in one city during but a comparatively short period. Nevertheless they indicate a lack of efficiency which is alarming when we consider the public has to pay the bills, and if you will take the trouble to contemplate with a discerning eye the methods of operation in any of our large cities, I am satisfied that you will be convinced of the manifest need of application of additional supervision, and intelligent regulation of the trucking business along the lines in which the railroads have worked at their handling of freight.

Car Detention Increasing.

It is not fair to the railroads or the public that the high grade of efficiency attained in one division of freight transportation should be handicapped by failure to improve the street transportation that occurs at each end of the railroad transportation, thereby causing an unnecessary increase to the consumer in the cost of the commodities transported. Were you as teamsters and shippers alone concerned, that would be another matter; but you must remember that from the time a freight car is placed in the freight terminal yard for unloading the railroad is at the mercy of the consignee, so far as that particular piece of equipment is concerned. The load may be such as could be readily removed in a few hours' time. Nevertheless, either through inadequate facilities for handling or because the time is not particularly convenient, or possibly because the consignee considers the full free time allowance as his inalienable right as prescribed by the national code of rules, this full free time—and in many cases more—is consumed in unloading. In saying "in many cases more", I speak conservatively, for, (to quote again from the I. C. C. report,)

\$9,379,524 of the gross income of the railroads of the country in 1911 consisted of penalties received for the detention of freight beyond the free time limit. Do not misconstrue this as being a desirable source of income to the railroad, because such is not the case. Every dollar collected for demurrage carries with it a loss of \$2.35 in the earning capacity of the cars held beyond the free time limit. Calculated on the basis of the demurrage receipts for the year ending June 30, 1911, the loss to the railroads in the earning capacity of their freight equipment amounted to more than \$10,482,700 above all revenues from demurrage.

The most serious aspect of the whole situation is the fact that the average car detention is constantly increasing. This is evidenced by the reports for New England for the years 1911, 1912 and 1913, which show an average car detention for these years of 1.58 days per car, 1.63 days per car, and 1.66 days per car respectively.

Effect on Terminal Facilities.

During all of this period the national code of demurrage rules was in effect. To be sure the increase is very slight, being but .08 of a day per car, but it assumes considerable proportion when based upon the 3,000,000 cars included in the figures from which this average was compiled. Expressed concretely, it amounts in the aggregate to 240,000 car-days; or, expressed in terms of cars, the railroads of New England have been called upon to increase their equipment by 800 cars within three years at a cost of nearly \$1,000,000 merely because of the inefficient system under which the freight is handled beyond the railroad's terminals.

If we pursue this line of thought a little further, we find that this increased freight car detention time not only makes a proportionate decrease in railroad working equipment, but seriously affects terminal yard facilities, the expansion of which is definitely limited by city real estate values and the conditions of the surrounding properties, inasmuch as the railroads are surrounded by industries that have secured available sites along the line of the carriers in order to be easily accessible to transportation facilities.

Railroads Seek Co-Operation.

In this quandary the railroads must seek the co-operation of the business world in order that they may work out the problem of securing the best transportation possible from the shipper to the consignee not only by the railroad but by street.

They have as far as possible increased their efficiency and reduced their costs of moving and handling freight to its destination and they have a right to expect that equal efficiency will be shown by the consignees on their part, but they find that while the railroad has spent enormous amounts of money and applied diligent study in its efforts to perfect this handling of freight, teaming through the streets has not progressed materially during the period in which the railroads have practically revolutionized the entire freight handling system.

The aim of management of manufacturing enterprises is always to effect the greatest economy in the cost of production that is consistent with the standard of quality and price of the manufactured product demanded by the consumer.

It has been evident in past years that a multitude of small railroads not operated as a system cannot produce the quality of transportation that is demanded in this great country in which we live. The result has been to amalgamate these small lines into powerful systems of railroads under one management and as a result we have the splendid system of transportation in the United States with which you all are familiar. However, when we consider the trucking industry in our various cities, we find a multitude of teaming concerns that are operating independently without any attempt of co-operation or a consolidation along the lines of greater economy or increased efficiency.

Scientific Study Essential.

It is commonly said that in our large cities the teamsters are not making any money, but are securing a bare existence in their particular field of industry. When we consider the lost motion and waste which characterizes the effort of these innumerable teamsters to handle their traffic without co-operation with others similarly engaged, it is not surprising that they are not growing rich. These various trucking concerns perform under contract about 60 per cent. of the street haulage of freight in our larger cities. Most of the business houses prefer to hire this service because they themselves have been unable to solve the problem of handling it for themselves largely because of failure to apply scientific study to its intricate propositions.

For years you gentlemen of the motor vehicle industry have been endeavoring to introduce modern machinery to replace the horse in this service and thereby produce a better quality of street transportation. You have not gone far enough. You have not endeavored to change the method. You have merely tried to improve the tools and so far you have done well; but improvement in the means without change in methods will go but a little way in the ultimate solving of the terminal freight problems. True, some slight advantage may be obtained, but so long as the efficiency of the apparatus is limited by the system under which it operates, the problem is no nearer solution than it ever was.

The Remedy Suggested.

The remedy is apparent. It lies in the co-ordination of the railroad and highway movement of merchandise, and a collaboration of the railroads and the teaming interests. I have been assured by some of the leading transportation engineers of your association that the accomplishment of this is possible, while a few years ago it was my privilege to review an engineering study of the highway freight movement in the city of Boston, which was made by one of them. His investiga-

tions supplemented those of the metropolitan improvement board of 1907, the scope of whose studies related principally to improvements in and extensions of terminals, docks and highways. His conclusions forcibly emphasized the necessity for some systematic method of handling this team tonnage, to accomplish which he advocated co-operation between the railroads and a consolidation of the trucking interests, resulting practically in an extension of railroad operating methods beyond their terminals. This plan is merely an acknowledgment of the unity of the terminal transportation problem, and appeared to me to be a logical solution of terminal freight congestion. Its principal advantage to the railroads lies in a train schedule system of operation and a marked reduction in the detention of freight on the railroad premises.

There is no reason why a powerful and efficient trucking organization of this nature should not only effect an enormous saving over present cost, but render greatly improved service through the employment of scientific and efficient methods of operation and a truck dispatching system worked out along the same lines as is the train dispatching and car distribution systems of our railroads.

This would prevent the use of a five-ton truck for carrying a small lot of freight weighing only a few hundred pounds, one or two miles across the city, by arranging to have that truck move via a definite schedule to its destination, picking up en route sufficient other parcels of freight to utilize to the fullest extent the carrying capacity of the vehicle.

Amplifying the Plan.

Furthermore an organization of this kind could probably establish central clearing stations at convenient points in the business districts to which light capacity vehicles could be run from nearby warehouses and from which consolidated loads could be moved in high capacity trucks to the railroad and steamship terminals, bringing back on their return similar heavy loads of inward freight for redistribution from the central station. Thus we could secure substantially an extension of the railroad operating methods beyond railroad terminals. Warehouse-to-warehouse delivery is successfully carried on in Europe and from the fact that over 60 per cent. of our city freight haulage in Boston, New York and Chicago is done under contract with truck men it is evident that the business world in our large cities would welcome an improvement along these lines. This proposition recognizes the substantial unity of the terminal transportation problem and the solution suggested will afford the railroads practically an extension of its system of operation beyond its present terminals. The efficiency of every transportation line is in a great measure limited by the adequacy of its terminal facilities. No railroad can be more efficient than its terminals permit it to be.

Confusion or congestion in freight terminals will react throughout the entire transportation line using that terminal, hence I am confident that the solution of terminal freight congestion lies along the lines of improved street transportation by the trucking industries, through consolidation.

This matter has been given a great deal of study by certain of your members and I am glad to present my observations on the subject from a railroad man's standpoint and suggesting what seems to me to be the logical solution of the problem of terminal freight congestion.

NEW YORK CONTINUES CALLAN LAW.

The New York legislators sidestepped practically every measure, pending when the legislature adjourned, that related to motor vehicle registration and control, and the Callan law, which became operative Aug. 1, 1910, will continue in force for another year, at least. The proposition that the registration tax be \$2 a year and that the vehicles be taxed as personal property in the communities where they were owned fell by the wayside, largely because it would have increased the revenues of the cities from local taxation and reduced the state revenue correspondingly.

The Murphy-Potter Company, Detroit, Mich., has changed its name to the Bronze Aluminum Foundry & Machine Company, this being in keeping with the character of its products. William E. Carpenter, after a service of three years as sales manager, has been made general manager of the company.

A quarterly dividend of 1.75 per cent. was paid by the Westinghouse Electric & Manufacturing Company on its common stock April 15, and a dividend of one per cent. on the common stock was paid April 30.

MAYO HEIRS BUY KNOX PLANT.

Springfield Property Sold for \$631,090, 75 Per Cent of the Appraisal Value.

The plant of the Knox Automobile Company at Springfield, Mass., including the real estate, buildings, machinery, patents, material and the unfinished products in the factory, have been purchased by Edward O. Sutton, acting for the estate of Alfred N. Mayo, former president of the company, whose claims against the property aggregate about \$1,000,000.

The sale was made by the trustee in bankruptcy, Charles G. Gardner, April 24, and after bids aggregating \$5855 had been made by individuals for three dwelling house properties, subject to incumbrances of \$7400, a bid of \$350,000 was made by Mr. Sutton. To the sale of the property vigorous objection was made by John P. Wright of Boston, who claimed to represent a majority of the stockholders of the company, who maintained that the consummation of the disposal would be fought by the committee on the ground that it was invalid, illegal and against the interests of the stockholders.

This bid was not accepted by the trustee in bankruptcy, who continued the sale until April 29, when a second series of bids were made by Mr. Sutton that aggregated \$631,090 for the property as a whole, and he stipulated that he would be willing to convey to the trustee or his nominees the three properties for which bids had been previously made, and which had been provisionally approved by the trustee. Mr. Wright again protested against the sale of the property, declaring it could not be legally sold.

The sale was approved by Trustee Gardner conditionally on the approval of the sale by the court, and it was stipulated in behalf of Mr. Sutton that his bid did not apply to any of the property unless he could obtain the whole of it. Mr. Wright stated that the sale would be contested by the stockholders' committee. The property was appraised at about \$1,600,000. The bid of the Mayo estate represented 75 per cent. of the appraised value of the real estate and machinery.

The understanding was that the plant will be continued in operation and that it will be devoted to the manufacture of pleasure cars, but there is probability of the continuance of the production of Knox-Martin tractors, which was a considerable part of the business for the year and a half previous to the sale.

The creditors of the Standard Roller Bearing Company, Philadelphia, Penn., have proposed that the receivers of the concern have a year in which to re-establish the business or to liquidate it. The company has an indebtedness of approximately \$1,500,000, this being to bondholders, banks and general creditors in proportions of about a third each. The quick assets are appraised at \$792,000 and the assets \$1,831,432.

STONE IS GENERAL MANAGER.

Motor Truck Club of America Activities Now Directed by an Executive.

The activities of the Motor Truck Club of America are now directed by General Manager Charles E. Stone, he assuming the duties April 1, and the belief of the members and officers is that with giving his personal attention constantly to its interests the scope of the organization will be greatly increased.

The club has for a long period been energetically promoting the use of motor vehicles in New York City in particular, and its methods have been of a character to attract attention throughout the country. The club was first organized by men directly connected with the industry and trade, and they immediately interested others owning and operating machines, and then turned to the investigation of conditions and problems having bearing upon or affecting the economical operation of all vehicles, both motor and animal.

The policy of the club has been broad, and instead of antagonizing interests of any character the club has sought to demonstrate the possibilities for transportation economies, bringing into conferences and rational consideration of local and state conditions men of prominence in municipal and state affairs, and promoting relations that are certain to be of material benefit. Various civic bodies have been invited to join with the club in every movement inaugurated and investigations have been begun that will lead to better systematization of traffic, improved facilities for traffic between different sections of the city and with New Jersey cities, improvement of the handling of incoming and outgoing freight at the stations, as well as the dissemination of information for the express benefit of those who own and operate machines.

The club has the benefit of a large and enthusiastic membership, that is anxious to promote its activities, and this has directed its endeavors in many channels, all of which are promising. When first formed the club was dependent upon the officers, who gave liberally of time that was valuable to them, and as the work of the club was developed many of them made material sacrifices for the promotion of the organization. The conditions became such that the progress depended largely upon the management, which could not be assumed by any one member. Eventually Charles E. Stone, a member who had been particularly active, who had been secretary and treasurer of the club and who has long been identified with the industry and trade, because of his personal concern and confidence in the work that could be accomplished, was elected general manager. He has assumed the duties of the office and has already inaugurated system and methods so that membership in the club will be of more practical value to any member, for he has available the resources of its organization and refer-

ence library, and the advice of a man who is intimately informed concerning all data that might be desirable.

Always available is the information bureau of the club, which has been created with the object of stimulating the use of motor vehicles, thus promoting the interests of the industry and, by the accumulation of data relating to transportation efficiency and economy, making possible the realization of the fullest practical utilities of machines in any service. As these data are in many instances of transportation departments in New York City and vicinity, where conditions are especially adverse and require extremely careful study to be met successfully, they can be accepted as dependable demonstrations of service.

NEW BOSCH SUPPLY STATIONS.

The following new supply stations are announced by the Bosch Magneto Company: Motor Supply & Tire Company, Akron, O.; Albany Garage Company, Albany, N. Y.; Augusta Garage, Augusta, Me.; Bangor Motor Company, Bangor, Me.; Bath Auto & Gas Engine Company, Bath, Me.; Motor Tire & Supply Company, Cleveland, O.; Troy Automobile Exchange, Cohoes, N. Y.; Motor Tire & Supply Company, Columbus, O.; Warren Garage, Elkhart, Ind.; Pearce Street Garage, Gloucester, Mass.; Blair Motor Company, Logan, Utah; Court Motor Car Company, Marietta, O.; George W. Roberts Electrical Works, Marysville, Cal.; Minot Auto Company, Minot, N. D.; J. P. Gayle Supply Company, Newport News, Va.; Port Washington Garage, Port Washington, N. Y.; Provo Machine & Foundry Company, Provo, Utah; St. Albans Foundry Garage, St. Albans, Vt.; Jensen Bros. Auto Company, Santa Cruz, Cal.; Gavin-Williams Company, San Diego, Cal.; Troy Automobile Exchange, Troy, N. Y.; Utica Cycle Company, Utica, N. Y.; Morgan & Williams Company, Warren, O.; Brass City Auto Company, Waterbury, Conn.

The Killen-Strait Manufacturing Company has succeeded the Killen-Walsh Manufacturing Company of Appleton, Wis., the reorganization creating a capitalization of \$200,000 and providing equipment and facilities for building tractors and freight highway vehicles. The experimental work has been concluded and the company now has designs that will be produced in such numbers as demand justifies. The factory will be considerably increased in size.

The Little Giant Sales Company, of which E. H. Habersham is president and general manager, has become agent for the Little Giant truck in Baltimore, Md., and vicinity and has established a station and offices at 1223-25 Park avenue in that city.

The Drednot Motors, Ltd., with capital of \$100,000, has been incorporated at Montreal, P. Q., to engage in the manufacture of motor wagons and trucks.

ELECTRIC VEHICLE PRACTISE.

Conditions of Electrolyte Indicated by Densities---Practical Hydrometers and Testing Sets--- Forms of Records to Be Used in Charging, and Formulae by Which a Lead-Acid Cell May Be Charged at High Rates.

By William W. Scott.

ASSUMING that a battery is in normal condition, that is, with the specific gravity of the cells approximately uniform, the standard efficiency—the amperage capacity—can be expected on discharge, and the useful work obtained will be practically what is estimated for it. If the voltage of any one or several cells be low this will have its effect upon capacity, and the work will be materially reduced.

When a battery has been shipped with a vehicle it is assumedly new, and it will gain somewhat, that is, with each successive charge and discharge the total amperage accumulated will gradually increase until a maximum is reached, and from that point the amperage will slowly lessen. The result stated will obtain if the greatest care is observed in operation, for this is a characteristic of a lead-acid cell, and eventually the battery will reach a condition where it will afford very little if any useful work. For instance, assuming a battery that will have a reserve after driving a chassis 50 miles, half of the distance loaded, when first installed, the capacity will be gradually decreased through use until the mileage that can be obtained may not be more than 10 miles, and it would be possible to use it until there was just sufficient power to move the machine 50 yards. But as a regular service is expected of any vehicle, and the condition of the battery would be known, when the power would be so reduced that it would be sufficient for the work, restoration of the battery would be imperative.

Emphasis has been made of the necessity of regularity in charging and discharging a battery, because this means not only greater efficiency, but a longer continuance of service, and the operating expense is minimized. Fully discharging is the most economical, and complete charging is decidedly the better, when these are possible, because there is minimum deterioration. Reference has been made to the loss of capacity—the lessened amperage—when the discharge rate has been hastened, and this means that there will be a loss of current that could be used proportionate to the rapidity of the discharge. The ratio of this reduction has been previously explained. Unless the voltage of the cell falls below 1.7, however, there is no material effect of the rapid discharge, aside from the loss of energy, but as charging is al-

ways an item of expense there is no good reason why a battery should be discharged at less than the normal rate, save in the event of emergency.

When a battery voltage falls to 1.7 and discharge is stopped there will be a slight recovery, for the voltage will rise within a short time, the degree of rise depending upon the rapidity of amperage reduction, but if this was slow the difference will be hardly noticeable. Generally speaking, however, there would be no greater consumption of energy with an indication of 1.68 volts at the end of a quick discharge than with 1.8 volts indicated with the normal rate of current flow.

The danger from excessive sulphation, resulting from over-discharge, is, however, of material importance, for this can only be reduced by the use of

Two Forms of Hydrometer Syringes Used for Testing Specific Gravity of Electrolyte and the Manner of Indication.

more current in charging, which means added expense, and there is probability of deterioration of the plates because of the necessity of reducing the sulphate to obtain the full efficiency of the battery.

There are the variables that must be considered in battery service, the condition of the element, the condition of the electrolyte and the temperature, and the influences of these can best be minimized by normal operation so far as this may be practical. Considering these variables in the order stated it will be understood that the greatest care that can be given the plates is by attention to charging, using a formula and adhering to it so far as this may be done. Undoubtedly the plates of cells will differ, but this is a condition that the batteryman cannot control, and so long as he gives careful attention to charging and discharging he is reasonably certain to have good results.

The condition of the electrolyte, however, is en-

tirely within the control of the batteryman. There is no good reason why the cells should not be examined frequently, and the electrolyte tested to ascertain its specific gravity. The height of the solution in the cells can be determined practically at a glance when one has had experience. The element submerged to a depth of a half-inch, covering the separators a quarter-inch, will substantially meet all requirements. Good practise dictates removing the cover plugs from the cells before charging, and, if, accessible, observation of the electrolyte may be made. But in the event the crates are not readily removable the depth of the solution can readily be determined with a strip of hard rubber placed in the opening in the cover. The rubber strip can be marked with the height the solution should have in the cells, and if inserted into the electrolyte the condition can be discerned instantly by the relation of the wetted surface and the mark. With the cells in a known position and with an inspection card note can be made of those in which the level is low. Having determined the height of the electrolyte in the cells, restoration of those that are low

the acid content of the electrolyte, and the gassing and slopping reduce the volume. As the height of the electrolyte is maintained by the addition of distilled water, the effect is a gradual reduction of the acid content, and eventually a density is reached when the efficiency is so much lessened that the acid must be replaced. Theoretically the restoration ought to be made very frequently, but in practical operation the efficiency is not found to be materially affected until there is a considerable loss of the acid content.

The reason for maintenance of the height of the electrolyte is that any portion of a plate that is exposed to the air will sulphate rapidly, and in a comparatively short time this sulphation will have reached a stage where it cannot be reduced by practical means. Not only this, the part of the plate that is submerged will be deteriorated by the relatively higher discharge rate in direct ratio to the decrease of the active area, for the work required of it will be more than the plate was designed to withstand. Incidentally, it may be well to state here that an element ought not to be exposed to the atmosphere save under the conditions that shall be stated. As the height of the solution will influence all plates in a cell and the separators, the need for giving it careful attention is obvious. Addition of distilled water is a work that requires comparatively little time, and for this reason ought never to be neglected. The loss of electrolyte from a leak will be considered elsewhere.

The density of the electrolyte, however, must be determined by hydrometer readings, observing the standards as established by the battery makers. The hydrometer may be one of several forms, but should be as large as is practical to use that the scale may be read readily.

Usually, hydrometers are calibrated to indicate from 15 to 35 degrees Baume and from 1.100 to 1.300 degrees density, but the Baume scale is not a necessity. The graduations, however, should show single degrees. The hydrometers usually used are primarily a syringe construction, consisting of a glass tube with a rubber bulb fitted at the upper end and a rubber or combination rubber and glass nozzle at the lower. Within this tube is a float consisting of a glass bulb with a long stem on which the graduations are marked. The nozzle is inserted into the liquid and the large rubber bulb compressed. A quantity of the solution is drawn into the tube and the marked float stem will indicate the density. If the float is much submerged the gravity is low, but if it rises the gravity is high. With this form of instrument the reading can be taken very quickly and at any convenient light if the work is at night. The forms of hydrometers differ, and the sizes vary, but the capacities are generally from two to three ounces, and the extreme lengths from 10 to 15 inches. If provided with flexible nozzles

A Typical Acid Testing Set, Consisting of a Tube, a Bulb Syringe and a Float Carrying a Graduated Scale.

can be made by the addition of distilled water. This should be done before charging is begun.

The loss of the electrolyte will result from evaporation, which will be more in hot weather than in cold; from gassing and from slopping. Should a jar be cracked there will be loss from leakage. The three causes first named are certain, and that last named is a possibility. The water will be diminished by evaporation, but both the acid and the water will be reduced from gassing and slopping. The loss in any case will be comparatively slow, save when a jar has been cracked. The evaporation must be through the vent hole in the cover plug, save when the battery is charging, and the loss from slopping may be from a loosened plug or violent movement, as from extremely rough road. The hydrogen and oxygen gas liberated in the form of bubbles will be impregnated with acid. With average conditions of operation the loss in several days, or even a week, will be really trifling, but there will be a loss. Evaporation concentrates

The largest size hydrometer that can be used conveniently is much the better instrument and the

A Practical Form of Charging Report Covering a Full Period by Hours.

Where the charging is by the gravity method it is necessary to make very frequent readings of the hydrometer, at the beginning of the charge and at stated intervals as it progresses, usually at intervals of a half hour, this giving 16 indications, but this is generally done with a pilot cell. With gravity charging a reading of the cell voltage may be made with a low reading voltmeter to establish the general condition of the battery, and then charging may be begun, the amper-

age being established at the given rate and continued until the cell begins to gas freely. At this point the amperage is reduced to the finishing rate and the charging continued to a point where the cell again gasses and the hydrometer shows no change in density.

The filling of the cells with distilled water is a work that can be done practically at any time. Should the density of the electrolyte be low the time for learning its condition accurately is at the conclusion of a complete charge. If the solution is weak no ill result will follow unless the specific gravity is extremely low, but when the electrolyte is strong there is increased local action and greater sulphation. Unless the battery has been fully charged the hydrometer may not indicate the exact condition of the solution, because of the sulphate that may not be reduced. This may be a result from insufficient charging, the sulphate accumulating and, because of ignorance, acid has been added to the cell. By this is meant that where the sulphate exists on the plates and more acid has been supplied because of the supposition that the solution is weakened, there will be greater strength of electrolyte than is necessary, which promotes local action.

The different makers all advise the cells be charged at stated intervals, from one to two weeks, for from one to two hours after the voltage and the specific gravity have ceased to rise, and when such a charge has been given the electrolyte should be tested. The lengthened charge will reduce the sulphation to an extent where the test of the cells ought to show the condition accurately, and if any of the cells are low in density these should be charged separately at a low rate. If this slow charging restores the cells to approximately the specific gravity of the others, one may assume that the cause of lessened capacity is confined

Charging Record Providing for 10 Vehicles with Readings Taken at Half Hour Periods.

to the cells—it may be sulphation or possibly a condition that requires other treatment than charging. But if the density does not increase and the temper-

ature does not rise it is a fairly safe conclusion that the electrolyte has been weakened by the addition of water. This loss may have resulted from a leak.

The specific gravity of the cells ought to be approximately uniform, and if when corrected for temperature the density is low electrolyte should be added. The fresh solution should be of the density specified by the battery manufacturers, and it can be prepared by the battery man. One part of 1.835 acid to 4.75 parts of distilled water will give a specific gravity of approximately 1.200 and one part of 1.835 acid to three parts of water will give a specific gravity of about 1.275. The mixing should be done in a clean glass or glazed earthenware vessel and the acid should be poured slowly into the water, and the solution stirred with a wooden paddle or spoon. The mixture will heat considerably, and should be cooled to room or atmospheric temperature to learn its correct density. This electrolyte can be added to the cells in whatever quantity is necessary to restore them to the gravity desired.

Record made of the voltage and the specific gravity of each cell is of material importance, as it is practical by comparison to determine variance, and to establish conditions that ought to receive attention. The importance of restoring low cells cannot be under-estimated. Low voltage cells will not only reduce the operating voltage of the entire battery, but will possibly be completely discharged and "reverse"

or establish a condition that will considerably lessen the efficiency of the battery, as well as being seriously affected from the excessive sulphation. While the charging is in progress cadmium tests can be made which will determine the state of the cells, but such tests cannot well be made when discharging unless during test discharges, which are advised from time to time as a means of learning accurately the condition of each battery unit.

The reason for charging a battery slowly is that there shall be the least deterioration from the reduction of the lead sulphate, and so long as a cell does not gas one can safely assume that the deterioration is as low as it can be controlled, and while supplemental or "boosting" charges can be given in the event of need it should be understood that the constant use of such excess current is not advised. "Boosting" as the term is usually accepted means the charging at higher rates than are specified as normal, and a battery may be "boosted" when completely or partially discharged, but the custom is to add to the charge sufficient energy to meet any unusual requirement. For instance, if a machine is to be driven further than the mileage that is practical with a full charge, the battery may be partially charged at a convenient place and the run continued, or where the work is such that the battery will be greatly reduced it can be given additional capacity when time will permit.

The following statement by the Electric Storage Battery Company relative to "boosting" with batteries of its production will demonstrate the possibilities of practical usage, and can be accepted as being authoritative:

"Modern methods of operating electric vehicles have developed situations where boosting can frequently be applied to advantage, and in many cases this is not realized by the vehicle owners or operators. It is our purpose here to show how boosting can be advantageously used and how it may be practically applied to batteries of the Exide types.

"The fact that overcharge at high rates is injurious to lead batteries has caused a very general misapprehension as to the ability of the Exide types to absorb current at high rates under proper conditions. The only factors in high rate charging which act injuriously are gassing and heating, and these appear only when more current is being passed through the battery than the plates can utilize. Therefore any current rate which the cells will absorb without gassing is not injurious, and it is upon this principle that boosting is applied. The more nearly discharged a battery is the higher charging current it can take, and by starting the charge at a high rate and tapering to a low rate at the end a large proportion of the discharge can be put back in a very short time.

"To illustrate what can be accomplished by boosting, the following table gives the additional battery capacity which can be obtained by constant potential boosts with the battery in different states of discharge:

Battery Charging Record to Provide Detail of Voltage and Amperage Readings for Half Hour Periods.

	30-Minute Boost, In- crease P.C.	40-Minute Boost, In- crease P.C.	One Hour Boost, In- crease P.C.
Battery fully discharged.....	22	38	50
Battery three-quarters discharged	19	33	42
Battery one-half discharged.....	15	26	32
Battery one-quarter discharged..	10	16	20

"Expressed in terms of mileage, this would mean that a vehicle, after having given 40 miles on a complete discharge, could have its battery boosted as follows:

"In 20 minutes so as to give nine miles additional.

"In 40 minutes so as to give 15 miles additional.

"In 60 minutes so as to give 20 miles additional.

"As a concrete example, suppose a delivery truck has to cover a mileage in one day beyond the capacity of the battery to deliver. Say that up to the noon hour 70 per cent. of the battery capacity has been used and it is desired to cover an equal distance in the afternoon. Under the straight daily charging system it would be necessary to have a spare battery and change over, or else provide a single battery of sufficient capacity for the entire day. Under the boosting system, however, the battery can be put on charge during the noon hour, and in that time it is possible to get in sufficient charge to duplicate the morning run. That is, 140 per cent. of the battery capacity is obtained in one day by simply giving a boosting charge of one hour at noon.

"A situation where the ability to boost is advantageous arises from the extra demand upon batteries under bad weather conditions. A battery may have ample capacity to give the desired mileage under normal conditions, but not when the roads are heavy, as after a snow storm, and the car draws an abnormally high current. By boosting when the conditions are bad, the battery can be made to meet the extra demand and no inconvenience result.

"There are several methods by which boosting can be practically applied to batteries of the Exide types, and the method to be chosen depends upon the available charging facilities and other conditions in individual cases.

"1. Constant Potential. Where conditions permit, this is probably the ideal method, since it is entirely automatic and requires little attention. It is applicable where there is available voltage of about 2.3 per cell of battery (e. g., 110 volts for 48 cells) and the charging equipment and wiring have sufficient capacity for current rates up to four or five times the usual starting rate charge. A voltage higher than 2.3 per cell can be cut down by having a set of counter electromotive force cells, figured at three volts per cell, which are always put in series with the battery when it is boosted. Thus, if the line voltage is 110 and the battery consists of 40 cells, there will be 18 volts to be taken up by counter cells, and six of them will be required.

"With the charging voltage thus fixed at 2.3 volts per cell, a battery in any state of discharge can be put on charge and will receive in a short time a large proportion of the amount of discharge which has been

taken out. The current will automatically taper from a high rate at the start to a low rate toward the finish, and no attention or adjustment is required. The cells will not reach the free gassing point or, under normal conditions, a high temperature, and therefore no harm will result from their being inadvertently left on charge longer than necessary.

"2. Approximate Constant Potential, with Fixed Resistance in Series with the Battery. When the time available for boosting is limited to one hour or less, the following method is often the simplest: Connect a rheostat in series with the battery and adjust the resistance so that the voltage across the battery terminals corresponds to that given in the battery below for the appropriate number of cells. The circuit can then be left without further adjustment for an hour or less, and the current will taper off as the voltage of the battery rises. The table is figured for a line voltage of 110-120, and the voltages given are too high for a boost of more than one hour's duration:

Number of Cells	Voltage at Battery Terminals
48	110
44	98
42	92
40	86
38	80

"3. Constant Current. In some cases it is more convenient to give a boost at a constant rate of current; as there is generally a limited time available, it is desirable to know under any given conditions what rate as safe. A convenient rule for determining this is as follows:

$$\text{Charging current (amperes)} = \frac{\text{ampere-hours already discharged}}{1 + \text{hours available for boosting}}$$

This gives the maximum current which can be used

TABLE OF BOOSTING RATES								
AMPERE HOURS DISCHARGED	TIME AVAILABLE FOR BOOSTING

EXPLANATION.—In the left hand column find the figure nearest to the ampere hours discharged from the battery; follow across to the column headed by the available time. The figure at this intersection is the current to be used.

EXAMPLE.—Ampere hour meter reading, 183 ampere hours discharged; time available for boosting, one hour. Start at 180 in the left hand column; follow across to the column headed 1 hour and find 90, which is the current to be used.

Tabulation of Amperage Required for "Boosting" Cells at Differing Stages of Discharge and for 15-Minute Periods up to Two Hours.

for the time specified without reaching the gassing point. The method is most conveniently applied where the car is equipped with an ampere-hour meter.

"As an example, suppose that 100 ampere-hours have been taken out of the battery, and there is one hour available for boosting. Then

$$\text{Charging current} = \frac{100}{1+1} = 50 \text{ amperes}$$

"In general, the above method will not put in as much charge in a given time as the constant potential method, and the current must not be continued beyond the time for which the rate is figured, as injurious gassing and heating will result.

"In order to save calculation, we give on the next page a table based on this formula. Knowing the ampere-hours discharged and the time available for boosting, the proper charging current, irrespective of the size of the battery, can be read off at a glance.

"When any considerable time for boosting is available and it is convenient to regulate the current at intervals, a greater amount of charge can be put in by dividing the time into periods and finding the current for each period separately.

"One of the methods outlined above is almost sure to meet the requirements of any individual case; but whatever method is used, remember:

"To obtain the advantages of boosting without injury to the battery, avoid gassing and keep the cell temperature below 110 degrees Fahrenheit.

"A general realization of the possibilities and advantages of boosting can result only in a wider field for the electric vehicle".

(To Be Continued.)

GENERAL MOTORS BUSINESS.

The business of the General Motors Company, of which the General Motors Truck Company is a subsidiary corporation, has shown a consistent increase thus far the present year, and the belief is expressed that by the end of the fiscal year, which will be July 31, the net profits will approximate \$10,000,000. The company has largely increased its gross sales during the last nine months, and this will probably be continued the greater part of the remaining period.

George H. Duck, president of the Motor Truck Club of America, has resigned as manager of the truck sales department of the Locomobile Company of America and has been succeeded by Frederick F. Colver of the Philadelphia branch of the company. Mr. Duck has not as yet announced his plans.

The Anderson Electric Car Company has appointed A. H. Dorsey, formerly with the Ontario Motor Car Company, Toronto, Ont., manager of sales at its Chicago branch, succeeding W. J. Gordon. Mr. Dorsey has had a long experience with electric vehicles.

RIGHT OF UNLIGHTED VEHICLE.

The supreme court of Iowa has decided that lights are not required at night by law on motor vehicles standing in the street, but not operated, and this decision is of material interest to all owners of machines of any character, for the provision of the laws with reference to lamps and lighting have been interpreted by police authorities as a rule to mean that whether moving or standing the number of lamps lighted shall be the same.

The question has been discussed, for the statutes generally specifically state "operated" with reference to any form of regulation established, and no determination had ever been reached. The case referred to was that of N. G. Kraschel of Harlan, who was charged with violating the law in not having the lamps of a machine lighted when it was standing at the curb of a street in that city. He was fined and appealed, carrying the case to the supreme court. The claim was made by the prosecuting attorneys that the city ordinance required the machine to have two front lamps and a tail lamp burning, either moving or stopped, so long as it was in the highway. The opinion of Justice Evans included the following:

"A standing car is not in the ordinary sense being operated or driven, neither is it proceeding in any direction. There is no more reason why a standing motor car should display lights than any other vehicle".

TO MAKE KEROSENE VAPORIZERS.

A kerosene vaporizer that is expected to be particularly adapted for motor truck engines has been perfected by E. P. Gould, chief engineer of the Affiliated Manufacturing Company, Milwaukee, Wis., and its manufacture will be begun by that concern as quickly as the preparations can be made. The statement is made that this vaporizer can be adapted for any of the present types of gasoline motors without changes, and that the fuel economy is approximately 66 per cent.

RUBBER GOODS COMPANY'S DIRECTORS.

The stockholders of the Rubber Goods Company, at the annual meeting in New York City, re-elected the old board of directors to serve for the ensuing year, as follows: W. S. Ballou, Nicholas F. Brady, Samuel P. Colt, F. W. Eddy, J. B. Ford, Ernest Hopkinson, C. A. Hunter, Lester Leland, R. B. Price, H. E. Sawyer and E. S. Williams.

M. E. McKenney, formerly advertising manager of Geuder, Paeschke & Frey, Milwaukee, Wis., has been appointed assistant sales manager of the Federal Motor Truck Company, Detroit, Mich.

FEATURES OF 1914 POWER WAGON DESIGN.

Characteristics of Machines That, Seemingly Incidental, Are of Material Importance in Increasing Efficiency and Reducing Expense of Operation.

Part II.

A STATEMENT has been made that the tractive effort or driving stress is exerted from the rear wheels through the radius or torque rods, and these are carried forward from the axle to the chassis frame, the connections being usually by brackets, these being either separate or combined with the jackshaft hangers, though in some instances combination is made with the spring hangers.

The radius rods are of numerous types, those used with chain driven machines extending from the rear axle to the side members of the frame, while with shaft driven chassis the rods are connected with a fitting or yoke on the torsion tube or with a cross member of the frame. Some constructions, however, use the same form of rod with shaft drive that is employed with the side chain. No rule can be applied, the designer being governed by experience and re-

mounted on seats on the rear axle, being free to rotate on the seats between two collars. Others of the same general design have a vertical pivot connecting the two forward sections, or the rods may be rigidly coupled to the rear axle and have a rotating movement on the hanger. Still another construction is that in which the rods are mounted so as to rotate on the rear axle, while the connection forward is by a spherical bearing on the jackshaft hanger, so that any stress is taken without material strain.

Much thought can be given to other detail of radius rod design, for the object is to equalize the driving and braking thrusts and to maintain the precise relation of the axle, as well as minimize the stresses upon the chassis frame. Side pressure is to be prevented so far as is practical. Of course the operating torque of the wheels and brakes is communicated

The Spring Buffer Radius Rod of the Velle Three-Ton Chassis, the Jackshaft Hanger of the Republic Ton Wagon, and the Spring Equipped Radius Rod of the Atterbury Two-Ton Truck.

quirements. The radius rods fitted with torsion tubes and carried on a single centre bracket in the frame are rigidly attached to the rear axle, one or more universal joints in the shaft compensating any variation in shaft alignment. With this method of drive the thrust is taken by the frame cross member and the angularity of the shaft is considerably reduced.

Variations in Design.

When the radius rods are carried from the rear axles to the frame side members the designs may be of several types, the purpose being to afford such protection as may be desirable against excessive stress by permitting comparatively free action of the axle vertically, and to a limited extent horizontally. Some constructions are with the forward ends rigidly connected to the hangers or brackets with an adjuster connecting the forward and rear sections, the rear ends being carried on vertical pivots in circular carriers that are

through these rods to the hangers and frame proportionately to the operating conditions. The heaviest stresses are developed when a machine is started when loaded, especially on grades, for the power necessary to move a weight from anchorage will be much more than is needed after movement has been begun, and when brakes are quickly applied, for quick stops must be frequently made. Another cause of excessive stress is contacting with a road obstruction. Because of the extreme violence of these strains the wear on the radius rods and connections is considerable, despite the size of the contacting surfaces, and as the chains and sprockets will wear, the rods must be lengthened to prevent excessive strains upon the springs and shackles, as well as avert possibility of the chains riding the sprockets and breaking.

Two American trucks have radius rods designed with heavy springs incorporated with the forward sec-

tions, there being a telescoping coupling to permit the spring action in addition to the usual provisions for compensation of vertical and horizontal movement of the back axles. The first of the designers to adopt this construction developed the Velie three-ton truck, and the same construction has been adopted for the two-ton chassis. The rods are of conventional length and construction aside from the spring and the coupling of the two sections, being mounted on the rear axle and the jackshaft hanger. The spring is helical, of square section metal, with comparatively little space between the coils. This spring surrounds the rod and the rear end is seated against a collar fixed on the rod, and the forward end contacts with a large adjustable collar, so that the tension of the spring can be adjusted to whatever pressure is desired. The spring is of such strength that the movement is comparatively slight, but there is a sufficient cushioning effect whenever the shock is excessive, this protecting the chassis as well as lessening the strains upon the tires. The springs are long, this being necessary because of the number of the convolutions and the minimized movement under

comparatively little thrust directly upon the chassis frame. The springs and connections are packed with grease and protected with leather boots, so there is practically no wear upon them. The springs are proportioned to the work, and the statement is made that the shocks are minimized in extreme conditions. The accompanying sketch shows a spring fitted without the boot.

Republic Service Brake.

The Republic truck service brake is installed on the jackshaft, the drums being of a conventional type with the brake bands contracting on them. The sprockets and the brake drums are carried on flanges on the shaft ends, and the jackshaft hangers, bolted to the frame, each have a bracket slightly below the centre of the shaft in front of the drum, on which the bands are hinged. The clamping lever of the brake is pivoted at the rear on a similar bracket, and the pull rod is carried forward in a direct line and coupled with the linkage. The jackshaft hanger also carries the forward end of the radius rod. The assembly is clean, in every way accessible and extremely simple.

Some Examples of Radiator Construction: The Sectional Vertical Tube Cooler of the Water-Cooled Chase Trucks, the New Type Installation of the GMC 2500 and 4000-Pound Machines, the Spring Supported Atterbury Radiator, and the Screen Protector of the Velie Three-Ton Chassis.

compression, and they are sufficiently back of the service brake drums to be easily accessible for any adjustment that may be desired.

Atterbury Truck Practise.

The rods installed on the Atterbury chassis, from one to five tons capacity, are fitted with heavy helical springs that have practically the same effect, being installed around a short telescoping section of the forward ends of the rods. The springs are much shorter, however, and the metal is round section, but the convolutions are close together. The design differs in that the forward section of the rod, which is carried on the jackshaft hanger, carries a fixed collar, and the rear collar is threaded on the rod, back of this being a large nut with a scored edge, against which the collar is seated. Turning the collar and the check nut will afford any adjustment of the spring, the tension being such as will permit a compression whenever the shock is excessive. The coupling is such that the spring will carry all the load when fully compressed, and there is

The system for cooling the motor of a power wagon is usually much larger than for a pleasure car because of the slow speed of operation and the lessened circulation of air. The water capacity is greater and the radiators are more expensive. The possibility of damage is materially increased and designers have directed much attention to the protection of radiators, and many have sought to minimize repair expense by using types that can be quickly restored in the event of accident. With the honeycomb or cellular radiator the opening of a seam will necessitate a soldering repair, which work cannot always be done by the repairer, and while cement will serve to stop leaks, this material is only regarded as useful for temporary restoration. Soldering generally lessens the radiating surface, and while a permanent repair is practical the work requires time and this means the loss of the use of the machine unless a spare radiator is available for such an emergency.

Many designers have adopted the tubular con-

The Forward Trunnion Supporting the Walter Power Plant, the Cross Spring Installation of the Little Giant Chassis, the Manner of Seating the Jack Spring of the Four-Ton Packard Truck, and the Connection of the Removable Front Frame Cross Member of the Walter Chassis.

struction, the copper tubes being finned to insure conductivity, and these are often installed in cast metal head and base tanks, with side members, or columns, of similar material. The tubes are sometimes soldered into the heads and bases, these making satisfactory joints, and occasionally rubber gaskets are used. Several radiators are built with the tubes in sections, so that in the event of damage these may be replaced, or the holes in the headers and bases plugged temporarily, and the machines continued in service. The sides or water columns and the tanks are bolted together, making a very solid assembly. These will endure much more severe usage, and have the added advantage of being easily and quickly repaired at comparatively small expense.

Chase and GMC Designs.

Two examples of tubular construction of recent design may be noted in the sketches of the Chase and the GMC machines. The radiators used for the two and three-ton water-cooled Chase trucks are of the vertical round finned tube construction, with the header a casting with wide fins. In this the tubes are soldered, as described. One or a number of the tubes could be damaged, and with these removed the tank could be plugged and the machine used. Repairing is a simple matter of soldering. These radiators are supported by lugs installed between helical springs in a

housing bolted to the chassis frames, and are not affected by chassis distortion.

The GMC radiator is a different form, but the principle is much the same, the header, base and side columns being one assembly, and into this frame is set a flat tube centre section with the tubing horizontal. The frame can be taken apart, the castings being bolted together, for cleaning, and a spare centre section can be installed with comparative ease. The radiator is installed within the frame, and the side frame members are extended forward, and the front cross member is the full width of the truck body, so that the radiator is unusually well protected. These radiators are used on both the 2500 and the 4000-pound machines.

Protecting Honeycomb Type.

The Atterbury chassis are fitted with honeycomb radiators that have very rigidly constructed frames, and these are mounted on two sets of helical springs that are carried on the frame front cross member. Two heavy bronze bushings are fitted in the frame member, and in these are sockets into which helical springs are fitted. From the bottom of the radiator base two bolts project vertically, and these are carried through the springs and holes in the bushings. Below the frame two shorter springs are seated against the web, clamped by collars secured by nuts on the bolt ends.

The Collar and Clamp Used on the Differential and Gearset Housing of the Kelly Five-Ton Trucks, the Forward Support for the Gearset Case of the Republic Wagon, and the Rear Cross Arm Supporting the Walter Unit Power Plant.

The radiators of the Velie three-ton trucks are a honeycomb type that are installed in a frame in which they are supported on springs, this minimizing any influence from chassis distortion, but protection is afforded by the curved front cross member of the frame, which is carried on extensions of the side members. As an additional protection a heavy wire screen is mounted in a frame of the same form as the radiator, and this frame is supported by bolts through a base flange and by a heavy bracket extending from each of the lamp brackets. The screen insures abundant circulation of air and prevents anything contacting with the radiator.

Walter Power Plant Suspension.

The suspension of the unit power plant of the Walter front-wheel driven truck is decidedly out of the ordinary, this installation being with a view of minimizing all effects of chassis distortion. The engine case is cast with a flange that extends back and encloses the lower half of the flywheel. To this is bolted a corresponding flange of the transmission gearset housing, so that the flywheel and clutch are

der the motor it may be drawn forward out of the chassis frame. The illustrations show the heavy frame front cross member with the supporting trunnion and the bolted connections with the side members, as well as the rear support.

Other Three Point Suspensions.

The three point support is also used for the suspension of the gearset case of the Republic truck, there being a heavy lug on the case that is fitted between the arms of a yoke bolted to the centre frame cross member, and supported by a bolt on which the lug will move when the chassis is distorted. The transmission gearset of the Kelly five-ton truck is bolted to a flanged extension of the pressed steel differential housing of the jackshaft. In this extension are the bearings of the gearset shafts, and to supplement this extension and to prevent the possibility of breakage from extreme stress a cast steel clamp is secured about it by bolts, and this is retained by a clamp that is carried across the differential housing and tightened by lock nuts. This affords great strength without necessitating much additional weight.

The Plunger Type of Accelerator Pedal of the Stewart Delivery Wagons, the Daimler Flexible Leather Coupling Between the Clutch and Gearset of the Stewart Machines, and the Special Winch Equipped Atterbury Truck for Freighting Laundry Machinery.

partly enclosed. The gear changing and the emergency brake levers are both mounted on the gearset case.

The forward end of the engine case is built with a centre trunnion that is mounted in a long bearing on the frame front cross member. Back of the dash and under the floorboards is an arched cross beam carried on the frame side members. From this the forward end of the gearset case is suspended by two long bolts that are fitted through heavy upper and lower lugs on the sides of the case, and secured by lock nuts. Any twist of the frame that would lift a side member will not cause any misalignment of the power plant, and no strain can be occasioned. This installation is so designed that by the removal of four bolts at either side of the frame front cross member this can be removed. A sling can be attached to the motor and it can be hoisted clear after breaking the fuel supply, water circulation, exhaust and ignition system connections and removing the two bolts from the rear support; or by placing jacks and horses un-

The installation of cross springs is usually made to a substantial frame member, because the upward thrust when the spring is deflected from the weight of a load or extreme shock is such that unless there is sufficient strength the cross member may buckle. One of the simplest forms of installation is that used in the Little Giant ton wagon, where a wide seat plate is used with a saddle, and the spring is secured to the cross member by clips that are bolted through the seat plate and the web. In the Packard four-ton truck chassis the cross member is a wide I section with the lower web widened to form the spring seat, the channels in the member are reinforced in the line of the bolts, and the upper web dropped over the reinforcements. The spring is attached by bolts through the saddle and both webs of the seat.

Daimler Flexible Coupling.

One of the claims made for the use of the Daimler flexible coupling, which has been adopted by several truck builders, is that this has a sufficient universal action at all times to meet practically any condition;

that it is light, the wear is almost negligible, and replacement is made at comparatively small expense. The Daimler coupling consists of two spiders having three arms, the centres being 120 degrees apart. Each of these is bolted to a series of three or more rings of specially prepared leather so that the bolt centres are each 60 degrees apart. With small sizes round washers are used on either side of the leather rings, but with the large sizes keystone washers are used, these better distributing the strain upon the leather. Most makers use these couplings between the gearset and the differential, either one or two as may be believed necessary, but in the Stewart 1500-pound wagon these couplings are used between the clutch and the gearset, an illustration showing the manner of installation.

A Special Equipment.

One of the oddities of special equipment was noted in an Atterbury truck seen at the Boston truck show. This was specially designed for the transportation of laundry machinery of considerable weight, and which would require a considerable crew of men to handle. To reduce the number of men the truck was fitted with a special winch, operated by the engine. The winch was simple, it consisting of a cross shaft with a drum at either end, outside of the driver's seat. This shaft was connected with the transmission gearset and so coupled that it could be operated in either direction, and controlled by two pedals. Two skids were carried in recesses in the deck of the body, so that these could be drawn out and placed at any convenient angle. The machinery was to be drawn into or lowered from the body on the skid, and with rope attached to it the freight could be handled quickly and without difficulty by the power of the engine, the rope being carried over sheaves directly back of each drum. Aside from the pedals, the sheaves and the drums, no evidences of the equipment appeared. From four to six men would have been necessary to handle the freight usually carried by this truck.

J. W. Johnson has been elected president of the Lee Tire & Rubber Company, Conshohocken, Penn., to fill the vacancy caused by the death of J. Ellwood Lee. Mr. Johnson is president of the Johnson & Johnson Company, manufacturer of medical supplies, New Brunswick, N. J., a concern with which Mr. Lee was long identified.

A quarterly two-day convention of the branch managers and salesmen of the Hess-Bright Company was held at Philadelphia, Penn., April 16-17, the first day being devoted to consideration of business subjects, and developing plans for sales promotion, and the second to factory inspection, amusement and a banquet.

The registration of motor wagons and trucks in Rhode Island was on May 1 very near the 1500 mark, and the registration of pleasure cars at that date exceeded 12,000.

OPENS BIG ELECTRIC GARAGE.

Largest Exclusive Truck Public Service Station Established in New York.

The Exide Battery Depot and Garage, established at 527-41 West 23rd street, west of Tenth avenue, is claimed to be the largest electric vehicle public service station in New York City, and the belief is expressed that it is not equalled in the country. The garage is conducted by the Exide Battery Depots, Inc., and the property occupied consists of a two-story structure that is used for office purposes, and a large one-story building that is given over to storage, battery room, stock room, repair shop, etc.

The building is accessible from the street by several entrances and is well lighted and arranged. Besides the various departments the main floor will store 100 machines of all sizes without encroaching upon the space that is necessary for working on and handling the machines.

The Exide batteries were for a considerable length of time handled by the New York Transportation Company, and when that concern was merged with the Yellow Taxicab Company the department was directed by F. F. Sampson, and in connection with the sale of the batteries the company maintained an exclusive electric garage in West 25th street, this having capacity of about 60 machines. This was given over to service vehicles and was the largest public service station of the kind in New York.

The business of the department has so much increased, however, and the demand for garage space for electric service machines in the central West Side section has been so insistent that the Exide Battery Depots, Inc., has been organized to give even broader and closer attention to the requirements of owners of wagons and trucks.

The garage has been specially equipped with every facility for affording service for battery users and this department is necessarily large, for a considerable area outside of the city itself is dependent upon this station for attention of all kinds with reference to maintenance. The other departments have been provided with the best of equipment for the differing requirements, quick service, economy of labor and time, and satisfactory results being the primary objects sought. The current is supplied for this station by the United Electric Light & Power Company.

George D. Wilcox, formerly sales manager of the Standard Motor Truck Company, Detroit, Mich., has been appointed sales manager of the Commerce Motor Car Company, which manufactures a 1000-pound delivery wagon, and has its general offices and factory at Detroit.

A dividend on preferred stock of the Peerless Motor Car Company, Cleveland, O., of 1.75 per cent., was paid by that concern April 1.

ADVERTISING RATES.

Information given on request. All advertising copy must reach this office not later than the 25th of the month preceding.

Anonymous communications not considered. Correspondence on subjects relating to trucks, delivery wagons, taxicabs, tractors, all motor driven farm, fire and municipal apparatus, the motor industry and the trade, will receive attention. Stamps must be enclosed to insure return of unsolicited contributions.

Entered as second class matter, February 25, 1911, at the Post-office at Pawtucket, R. I., under the Act of March 3rd, 1879.

REAL ROAD ENGINEERING.

Road engineering of today demands, assumedly, materials that will endure. Practically all authorities are agreed that a macadam highway that will last for a reasonable period with animal traffic is worn to greater ratio when the travel is augmented by motor vehicles. The macadam road, when the surface is bound with bitumen, will endure for years with comparatively trifling repairs, but the surface will quickly disintegrate from the hoofs of horses.

The macadam construction is regarded as an improvement when compared with gravel for general highway purposes, and the expense is greater. Well built gravel road, however, is a much better construction for combined animal and motor traffic than is macadam, because it is consolidated by travel and can be repaired by surfacing, while there is never internal destruction such as develops in all macadam ways. Oil will suppress dust and eliminate insects. The travel on a gravel road, provided reasonable attention is given to filling depressions whenever they develop, will keep it consolidated from the surface to the sub-grade, whether the vehicles be driven by motors or drawn by animals.

The gravel road is worthy of consideration because it costs less than macadam, can be more easily maintained, endures better where there is mixed traffic, and the material is generally obtainable. The general impression is that the gravel road is obsolete. As a matter

of fact its value is not understood by the public and is seldom realized by engineers. Well built, it is practical and comparatively much more economical. The development of the possibilities of this road is an opportunity for real highway engineering.

MOTOR TRUCKS IN WARFARE.

With the prospect of at least military occupation, and possibly warfare, the Mexican situation from the viewpoint of highway transportation is giving the experts of the War Department some anxious hours. The destruction of existing lines of railroad sufficiently to prohibit their use can be easily accomplished, but roads can generally be passed over with temporary repairs, even if damaged. In the event of roads being made impassable, detours are generally possible. The United States has made comparatively little progress with the use of trucks in military operations, which policy is diametrically opposite to those of the European nations, which have anticipated and provided so far as possible for just such exigencies as now exist in Mexico.

Should there be operations in Mexico the advances will necessarily be made by road, because of the comparatively small railroad mileage and the probability that these will be useless until controlled by and repaired by Americans. This being so, the initial army transportation will be dependent upon either animals or motor trucks. To what extent machines would be used is problematical—not from regarding them as experimental, but because of the character of the country in the first instance, and the impossibility of procuring immediately a sufficient number to meet the requirements, without taking those now in use.

TIRE DAMAGE BY OVERLOADING.

With the guarantee of 7000 miles, now very generally applied to gasoline freight vehicle solid tires, which must be obtained in 12 months, there is every reason why owners of machines should give careful attention to economy, and there is no factor of greater importance than limiting freights to vehicle capacity. There is every reason why this care should be taken. The machine driven 50 miles daily for 300 days will cover 15,000 miles annually, and if tires endure the full mileage guaranteed more than two full sets would be necessary. The assumption may be that tires are paid for on the basis of miles driven, but this is not the result obtained in actual service. There is always shrinkage of mileage, no matter how accurate or liberal the adjustments, and with less miles guaranteed and no reduction of price the economy for the purchaser is to get greater results than he is assured of. One of the most certain safeguards is to limit the loads to the vehicle capacity, and to be certain that the machine is equipped with sizes of tires that will endure. If the mileage obtained exceeds the guarantee the owner is saving money.

RESULTS OBTAINED IN MUNICIPAL SERVICE.

Maintenance Figures Revealed by Annual Report of Street Department in New Bedford, Mass.--Relative Economy of Motor Apparatus in New York City--News Briefs.

INTERESTING figures are made public by the City of New Bedford, Mass., in connection with its municipal garage, the annual report concerning which was filed recently with Mayor Ashley by the clerk of the street department, in charge of its maintenance. The total cost of operation, including garage expenses, gasoline and oil, tires, repairs and chauffeurs' salaries, was \$13,039.95, against which was credited \$3100.51, the amount paid to the street department by other city departments for the use of different cars, bringing the net cost down to \$9939.34.

Aside from the fire department vehicles, the city

for municipal machines, and the plan is meeting with wide acceptance in various sections. The report referred to above indicates the wisdom of such action.

ESTABLISHES A PRECEDENT.

Toledo, O., not only has taken the initial step toward the complete motorization of its fire and police departments, but has established a precedent among American cities, in the purchase of five Willys-Knight cars. This is, so far as is known, the first in-

owns a seven-passenger Locomobile, used by the mayor; an Abbott-Detroit pleasure car, used by the police; Franklin touring car, utilized by the superintendent of streets; Franklin runabout, employed by the assistant superintendent of streets; White three-ton truck and a Johnson wagon. In addition, an old Franklin machine was in service during the first five months of the year, at the end of which time it was sold.

A portion of the city barn was remodelled into a garage, which was placed under the supervision of the street department. Instead of purchasing machines for those departments which would have use for them only a part of the time, it was decided to make a charge for such service in conformity with the figures prevailing in New Bedford for machines hired outside. The accompanying table sets forth the result of the experiment, which is regarded in every way as a success, and affords valuable data respecting the cost of machines in municipal service.

New Bedford is not the only city in the country to adopt this method of caring

stance in which cars equipped with the Knight sliding sleeve motor have been purchased for municipal service.

Two of these machines will be fitted, upon special order, as flying squadron cars for the two principal police stations. The three others will be equipped as roadsters and will do duty as battalion chief's cars in the fire fighting squad. Besides utilizing Knight engines, these chassis have Lanchester spring suspension, worm driven rear axles, etc. The motors have four-inch bore and 5.5-inch stroke, developing 40 to 45 horsepower, according to the maker's rating.

Three-Ton White Truck in Service with the Street Department in New Bedford, Mass.

STREET DEPARTMENT COSTS.

The annual report of the street department in Lynn, Mass., shows the cost of operating five trucks owned by that city. Of these, three were purchased during the past year, and the report shows the cost of the chassis. The body work was done by the street department in its repair shop, except for the Teel-Woodworth truck, the body for which was built at the factory.

This is a three-ton machine, having a 40 horsepower motor, and being fitted with a tank for street sprinkling. The Standard is also a three-ton, 40 horsepower machine, and this and the three-ton White chassis were fitted with dumping bodies. The Federal mentioned in the report has been in continuous service for 10 to 14 hours daily, almost without cessation for nearly two years. The figures include a new set of tires. The report follows:

	Cost	Body	Running Expense
White	\$3515	\$261.36	\$241.63
Teel-Woodworth	2750	78.57	240.12
Standard	2800	176.21	551.16
Repairs.			
Federal		\$413.16	\$722.33
Ford		427.14	440.30

FOR ASHES REMOVAL.

Acting in co-operation with the engineers of the New York City street cleaning department, the White Company, Cleveland, O., believes it has solved many of the difficulties attendant upon the removal of ashes and garbage by the installation of a new type of dumping body, built on an underslung frame. The body is 13 feet three inches long by seven feet six inches wide, and has a capacity of 252 cubic feet. The sides are made up of removable sections, which facilitate loading and make it unnecessary for the crew to lift refuse receptacles more than waist high. The top is completely covered by sectional doors, a feature of decided sanitary importance.

The truck is designed to be used for carrying all kinds of refuse, as well as for ashes and garbage. At the disposal plant or dump, the load is deposited at

any prescribed spot, the unloading being accomplished by a standard White dumping mechanism, placed out of the way horizontally along the frame. The contents of from 110 to 122 cans of ashes, the equivalent of five one-horse cart loads, can be carried by this machine at a time.

In the district where this truck is now working, the haul to the dumping place is three miles. The machine covers this distance in 14 minutes. One man drives and operates the dumping mechanism. If the truck travelled only as fast as a horse drawn wagon, it would be doing the work of five horse, five carts and five men, but it travels three or four times as fast, hence, it does the work of 15 to 20 one-horse carts.

MARTIN COMBINATION WAGON.

An accompanying illustration presents the Martin combination chemical engine and hose wagon, type B, made by the Martin Carriage Works, York, Penn. This is fitted with a four-cylinder, four-cycle, water-cooled, T head motor, with cylinders cast in pairs, and with bore of 4.25 inches and stroke of five. This gives a rating, under the S. A. E. formula, of 28.9 horsepower, but the maker claims it will develop 40 at 1600 revolutions a minute. Ignition is by high-tension magneto. Lubrication is by force feed.

The clutch is a multiple disc member, and the sliding gear transmission affords three forward speeds and reverse. Final drive is by side chain. Service brakes operate on the jackshaft, and the emergency, on rear wheel hubs. Springs are semi-elliptic front and rear. The wheels are of select second growth hickory, artillery hubs, with extra large flanges specially designed for fire department service. Tires are 36 by 3.5 inches in front and 36 by four in the rear. The wheelbase is 124 inches and the tread, 58 in front and 60 in the rear. The speed is 30 miles an hour, although this may be increased by the use of pneumatic tires.

The body is made of thoroughly seasoned lumber, properly ironed and braced. The capacity is 1000 feet of 2.5-inch double jacketed fire hose. The pilot seat is an attractive racy type, with ample arm room, and railings and fittings are in nickel or brass. The equipment includes: One thousand feet of 2.5-inch fire hose, two 35-gallon hammered copper tanks, 2000 feet of .75-inch four-ply chemical hose, shut-off nozzle, two acid receptacles, hose spanners, wrench, hose basket, two lanterns, alarm bell, one 20-foot rapid hoist extension ladder, one 12-foot roof ladder with patent folding hooks, two extinguishers, axe, 25 feet of rope, etc.

Type B Combination Chemical Engine and Hose Wagon, Made by Martin Carriage Works, York, Penn.

MOTOR VS. HORSE EQUIPMENT.

Officials of the fire department in New York City recently made public some very interesting figures, based upon their experience with motor driven apparatus and with horses. According to this authority tractors for engines and ladder trucks cost \$3750 each, and their life is 20 years. The annual cost of maintenance is: Depreciation, \$186; 100 gallons of gasoline, \$20; 10 gallons of lubricating oil, \$12.60; repairs, \$200—a total of \$418.60. Three horses, for the same purpose, cost \$350 each, or a total of \$1050, and the life of a horse in fire department service is seven years. The annual maintenance is given as: Depreciation, \$150; forage, veterinary services, shoeing, stable equipment, harnesses, etc., \$750—a total of \$900, which exceeds that of the tractors by \$481.40, or in 20 years, the life of the tractor, by \$9628.

The officials also state that the cost of a motor hose wagon is \$4045, and its life 20 years. Its annual maintenance is placed at: Depreciation, \$202.50; 100 gallons of gasoline, \$20; 10 gallons of lubricating oil, \$12.60; repairs, \$100—a total of \$335.10. Two horses, required for the same kind of apparatus, cost \$700, and their maintenance at \$250 each is \$500. Depreciation is placed at \$100. This gives a total of \$600, which exceeds the annual maintenance cost of the motor equipment by \$264.90.

It may be admitted that the figures for horses will vary materially in different localities, and that other cities will not experience the same results that appear to have been obtained in New York. However, it is possible to include some extra expense for repairs to the fire station, which can be charged directly to horses. And, of course, there is the additional question of the decreased room necessary when motor apparatus replaces horses, an item that comes very much into the consideration when new real estate is to be acquired or when a new building is being erected.

NEWS FROM VARIOUS CITIES.

For Spreading Hot Tar—White Company, Cleveland, O., announces sale of three five-ton trucks to Good Roads Company, a contracting firm in Baltimore, Md., for use in spreading hot tar and other road binding materials. The tank bodies will be built with a steam generator and a series of interior steam pipes for maintaining the tar at the proper state of fluidity, and the power transmission will operate an air compressor to force the fluid through the passages to the spreading outlet.

To Purchase Apparatus—Robert Boone of Asbury Park, N. J., has been appointed chairman of a committee representing the North Asbury Engine and Hose Company, to purchase automobile apparatus. This is to be similar to that now used by the Wesley

and Neptune companies, with electrical equipment, and small hose and air pressure tank, in addition to the regular hose supply.

Accepts Robinson Pump—The Independent Hose Company, Red Bank, N. J., has taken delivery of a Robinson triple combination pumping engine, made by the Robinson Fire Apparatus Manufacturing Company, St. Louis, Mo. According to the terms of the contract the machine was required to pump 800 gallons against 120 pounds net pump pressure; 300 gallons against 200 pounds, and 320 gallons against 250 pounds. The official test was made under the supervision of engineers representing the National Board of Fire Underwriters.

Detroit Buys a Paige—The police department in Detroit, Mich., has added another machine to its already extensive equipment, this being a 36 horsepower Paige Speedway model, made by the Paige-Detroit Motor Car Company of that city. An accompanying illustration shows Sergt. Staples, of the division which

Paige Speedway Model, Recently Acquired by the Detroit Police Department.

devotes its energies to regulating speed, seated in the new car. He formerly used a motorcycle.

Want Motor Patrol—The Ninth District Improvement Association and the Village Improvement Association of Melrose, in the town of Wakefield, Mass., are engaged in working up public sentiment in favor of purchasing a motor police patrol, capable of being converted readily into an efficient ambulance. It is pointed out that a town of that size, possessing no public hospital and no readily available ambulance, and containing numerous factories, should be equipped to handle cases of emergency or accident in the most efficient manner.

In the Market—The following cities are considering the purchase of motor fire apparatus: Fort Wayne, Ind., tractors; Nahant, Mass., pumping engine; Erie, Penn., aerial truck; Knoxville, Tenn., three pieces; Jamestown, N. Y., combination pump, chemical and hose car; Holland, Mich., combination chemical and hose wagon; Cornwall, N. Y.; Somerset, Penn.; Fullerton, Cal.; Watkins, N. Y.; Danbury, Conn.; Anacortes, Wash.; Avalon, N. J.; Waverly, N. Y.; Warren, Mass.; Watsonville, Cal.; McComb City, Miss.

NEWS FROM THE FOREIGN TRUCK FIELD.

French Army to Increase Its Tractor Equipment as Result of Recent Military Trials--Four-Wheel Drive Machine for German Government--Notes from Abroad.

AS A result of the recent French military trials, in which 13 four-wheel driven tractors competed with splendid success, it is a foregone conclusion that the army will largely increase the number of such vehicles employed, particularly in the artillery corps. The entire 13 machines, each of which hauled two trailers fully laden, completed the test without mechanical difficulty and in good condition. Two types of machines were tested, light vehicles hauling maximum loads of 13.5 tons, and heavy, hauling loads totalling 22.5 tons.

Four makes were represented: Panhard-Chatillon, Latil, Renault and Schneider. Two of the four Panhards were fitted with Knight engines. The machines left Rheims on a 600-mile trip over all sorts of roads, arriving in Paris at the end of two weeks. At no time did any of them receive outside help, and, although some often became embedded in mud or sand, they always were able to extricate themselves under their own power.

At the conclusion of the run the military jury decided to include a series of supplementary tests, dealing with hill climbing ability, the use of winches and capstans, brakes and the power of operating across country with thick mud prevailing. The first of these comprised climbing an 11 per cent. grade with an S turn in the middle. Tractors were required to go half-way up with two trailers, stop, unhitch the trailers for a brake test, and finally haul the trailers to the top by means of the capstan.

The result of the trailer brake test was uniformly unsatisfactory. When the 15-ton loads were left to themselves it was impossible to hold them on the hill with their own brakes. These were of the ordinary horse wagon type, brought into contact with the steel rim of the wheel by a screw or a lever. In every case the diameter of the shoes was found to be too small.

The supreme hill climb was on a 22 per cent. grade, with a right angle turn at the bottom. This was

climbed by the tractors only, with full load on their platforms, and all went up with comparative ease. Each machine was stopped in the middle for brake tests, and in every case it was possible to hold the tractor with two sets of brakes, but in some instances it was difficult to stop them when they were allowed to run backward. The Schneiders, with external wood blocks, were the only ones capable of stopping with one set of brakes.

Cross country tests were made on a military ground near Paris, where for nearly a month persistent rain had made conditions as difficult as could well be imagined. These trials had in view the efficacy of the various paddles and other appliances for working in mud. The Latils and one of the Panhards were equipped with a steel rim with deep projecting ribs bolted to the side of each wheel. Another Panhard made use of hard wood strips placed across the wheel at very frequent intervals and attached by chains going between the spokes. Still another Panhard device consisted of a ring of metal plates forming links and completely covering the rubber tires. An almost square block of wood was pivoted to each of these links, forming a series of wood paddles around the wheel. The Schneider machines were equipped with a pair of steel running boards, which could quickly be taken off and made use of to get over ditches and soft places. Heavy chains around the tires were utilized, except in the very worst spots.

GERMAN FOUR-WHEEL DRIVE.

Accompanying sketches set forth the constructional details of the new Ehrhardt four-wheel drive wagon, recently supplied to the German military authorities by Heinrich Ehrhardt, Dusseldorf. The machines furnished were equipped with guns adapted to be fired at balloons, aeroplanes, etc.

The motor is a four-cylinder unit, with bore of 130

mm and stroke of 150 mm (5.1 by 5.9 inches), rated at 50 horsepower. The two central bearings of the crankschaft are carried in the upper half of the base chamber, while the two end bearings are divided, one part being supported in the top half and the other in the lower portion of the crank chamber.

The change speed gear, which is connected to the

Plan View of Ehrhardt Chassis, Recently Delivered to the German Military Officials.

engine through a leather faced cone clutch, is adapted to give four speeds forward and a reverse. There are three shafts in the gearbox, these all being located in same plane, one above the other. The sliding pinions are mounted on the top shaft, which is castelated for the purpose. The gears on the two lower shafts are constantly in mesh, the lowest carrying a differential gear, and also are provided with universal joints at each end, which transmit power through propeller shafts extending forward and backward to the front and rear axles, respectively, both of the last named being driven through bevel and differential gearing.

In the front, as well as in the back axles, the live shafts are enclosed in a casing. On the front axle, built up with the steering pivots, is a dust and grease tight casing which encloses a series of bevel pinions, enabling the drive to be transmitted to the front wheels at whatever position they may be turned under the action of the steering wheel.

The rear wheels, which are mounted on the axle casings, and receive their driving effort through dog clutches fitted to the ends of the axles, are of special type, built up of sheet steel discs and shod with twin solid rubber tires. On each side of the wheels extension rings are bolted, so that when the vehicle is travelling over soft ground, into which the tires may sink, there is a rim surface 15 inches wide, which assists in preventing the loss of traction.

CARRYING HORSES BY MOTOR.

Dissatisfied with the conditions under which his race horses were being carried from his training stables near Paris to the various race courses in England, Edmond Blanc has instituted, for their benefit, a special motor service between France and England. When sent by rail, race horses are often rendered nervous and are put out of condition to such an extent that they do not do justice to their trainer.

The new motor service consists of a Latil front drive chassis, to which a special form of horse box has been adapted. One chassis is kept in readiness at the training stations, and when the horse has been led into the van the latter is raised by a crane and deposited thereon. In a few minutes it is fastened down and it is quickly on the way to Boulogne. On arrival at this port the driver takes his vehicle to the quay, and the van is raised from the chassis and deposited on the deck of the steamer.

A similar Latil chassis is in waiting at Folkestone, the van is placed upon it and fastened securely, and the journey is continued to the course on which the horse is to make its public appearance. Thus, from the time the horse leaves the

French training ground until its arrival on the English turf, it is not taken out of its box. The actual journey, too, occupies slightly less time than by rail.

Everything possible is done for the comfort of the horse. The van is suitably padded, and in the fore portion there is a compartment for the trainer, who is also in communication with the driver. The vehicle is mounted on twin pneumatic tires front and rear. With the front drive system, as employed with the Latil, which is made in America by the Walter Motor Truck Company, New York City, there is no mechanism to the rear of the front axle, thus there is an entire absence of noise which might distress the animal.

BOHEMIAN MOTOR PLOW.

Leurin & Klement, Ltd., Jungbunzlau, Bohemia, Austria, somewhat well known in the industry through the manufacture of the Klement pleasure car, has produced a new motor plow, following closely, in general appearance, the Stock machine made in Germany. The engine is mounted in front on a long frame, which is carried on two large diameter driving wheels. Attached to the other end of this long balanced frame is the plow frame proper, carrying six shares, the rear being mounted on a special guide wheel.

The engine is rated at 80 horsepower, and is a four-cylinder unit, cast in pairs. Ignition is by Bosch high-tension magneto, and a motor starter is fitted. The clutch is a cone member, specially designed to provide easy engagement. The transmission affords three speeds forward and reverse, and is so arranged that it is impossible to change speeds without declutching. The three speeds are two, three and 3.75 miles an hour.

The large driving wheels are fitted with removable paddles, for affording traction in soft soil, and when these are detached, it is possible to operate the machine over ordinary roads without difficulty. Two men are required to operate the plow, one of whom faces forward at the steering wheel, while the other faces backward, being seated at a lower level, to manage the plow share frame. Both seats are located a short distance behind the driving wheels.

Side Elevation of Ehrhardt Four-Wheel Drive Chassis, Illustrating Relation of Components to Each Other.

WILLYS UTILITY ABROAD.

It is seldom indeed that British municipalities depart from what appears to be an unwritten law with respect to goods made in Great Britain. It is therefore somewhat surprising to learn that the police department in Leeds, England, has been using a specially equipped Willys Utility chassis, made by the Willys-Overland Company, Toledo, O., and with such success that English newspapers felt constrained to state that the men assigned to this vehicle were particularly efficient in the discharge of their duties.

The 16 policemen shown in an accompanying illustration composed a "flying squadron", assigned to special duty in Leeds during the recent industrial strike in that city and vicinity. For three weeks they were on duty night and day, ready for instant transportation to any quarter in which trouble might occur. Of course, the machine was subjected to the same requirements, and it was almost constantly employed in

Willys Utility Chassis Utilized by Flying Squadron of Police During Recent Strike Riots in Leeds, England.

rushing the officers from one part of the city to another. The success which attended the initial use of an American machine for such work is expected to result in increased business in this type of vehicle.

FOREIGN NEWS NOTES.

Market for Motor Omnibuses—Reports from Roumania state that there is a decidedly good market for motor omnibuses, which are wanted for developing business in many districts inadequately supplied with railway facilities.

Fire Apparatus for Russia—Russian municipalities are beginning to take interest in motor driven fire fighting apparatus, as evidenced by a recent order for two German machines given by the department in Kiev. Both are of the Bussing make, one a pumping engine capable of delivering 440 gallons a minute,

and the other an extension ladder, fitted with an electric motor designed to turn the ladder through 360 degrees when inclined at an angle of 65 degrees.

Austrian Import Figures—There was a large increase in the importation of foreign made commercial motor vehicles into Austria last year, the returns showing a total of some \$850,000 as compared with \$580,000 for the previous year. The largest number of machines imported were from Germany, with France, America, Great Britain and Belgium following in that order.

Agricultural Trials in Scotland—Regulations have been issued by John Stirton, secretary of the Highland and Agricultural Society, 3, George IV bridge, Edinburgh, Scotland, for the exhibition trials of motor agricultural implements, which will be held in that city some time this autumn. In order to secure entries from foreign countries, the society has decided to allow a sum equivalent to the freight and cartage from London to Edinburgh.

Adopts Easy Payment Plan—Another example of the methods adopted by British manufacturers of motor vehicles and their dealers to offset the effects of the so-called American invasion, is noted in the recent announcement of the Bentic Motor Supply Company, Manchester, England, that it is prepared to supply Belsize machines on easy payment terms. These include a deposit of 25 per cent. of the cost at the time of sale, and the remainder in monthly installments.

German Export Figures—According to the figures recently made public in Germany, the exportation of commercial motor vehicles during 1913 reached a valuation of some \$3,250,000 as compared with \$1,900,000 in 1912. Twenty-five per cent. of the machines were shipped to Russia, Brazil, Austria, Roumania, Turkey, Servia, Finland, Great Britain, Holland, Italy, Argentine, America and Switzerland following in that order.

More Motor Mail Vans—The general postoffice surveyor for the northeast district in England is inviting tenders for the conveyance of mail in motor driven vans between Leeds and Boroughbridge, Yorkshire, for a period of three years. This is another step in extending this type of service in many sections of Great Britain.

Gramm in St. Petersburg—A contractor in St. Petersburg, Russia, is utilizing a Gramm truck, equipped with Firestone tires, in handling lumber and structural iron work between that city and Tsarskoe-Selo.

NEW COMMERCIAL CAR ACCESSORIES.

Carbonox.

Carbon is present in the cylinders of the internal combustion engine, the amount of the deposit depending upon

the grade of lubricant and the quantity utilized. Formerly it was deemed necessary to dismantle the motor to remove it, but in these days it can be displaced easily. The Northwestern Chemical Company, Marietta, O., has been marketing for some time a carbon remover called Carbonox, a fluid, which is injected into the cylinders. The preparation does not dissolve the carbon, but attacks the charred oil that fastens the flakes of carbon to each other and to the cylinder, piston head, etc.

The method of use is simple. Carbonox comes in a can having a detachable spout and by means of the latter the fluid is injected through the spark plug opening. The result is that the carbon is loosened and is blown out in the exhaust. The amount present may be noted by holding a sheet of paper under the outlet. One of the qualities of Carbonox is that it provides an inexpensive method of keeping the cylinders free from carbon, as the cost a cylinder is but a few cents.

Knopf Recorder.

The Knopf Bros. Manufacturing Company, Inc., 2071 Seventh Avenue, New York City, has brought out a new type of mileage recording instrument, the operating mechanism of which is contained within a case which is attached to the wheel by several screws entering the spokes or hub flanges. The screw heads, however, are inside the case, which is provided with a lock.

The mechanism is suspended inside by ball bearings with a weight to maintain it in its proper position. The odometer is operated by a cam located inside the case, which strikes a roller once during each revolution of the road wheel, actuating an arm which moves a ratchet wheel one notch. The odometer registers to 10,000 miles and repeats, but it cannot be set back without completely disassembling.

A cylinder in the upper end of the odometer rotates once for each mile travelled by the car, causing an arm to oscillate with a slow, continuous motion, once for each mile. The arm carries at its upper end a stylus, which produces a record on a tape as it is drawn out from a little round box at the top.

At the right of the weight is a clock which will run for 36 hours on one winding. It is geared to a large drum surrounding the central wall of the instrument, upon which the tape is wound at such speed that the stylus comes opposite the hour marks at the proper time. The tape is sensitized so that the pressure of the metallic stylus traces a line upon it, and it is graduated into three-minute periods, two inches being allowed for each hour. The recorder registers starting, stopping and operation of the vehicle, as well as the rate of speed, and they are outlined on tape.

Farnsworth Generator.

The Farnsworth gas generator, marketed by the Distillate Motor Equipment Company, San Francisco, Cal., makes possible, it is claimed, the operation of a motor car with kerosene, distillate and other low grade fuels. The exhaust gas is utilized for raising the temperature of the fuel, and the generator shown in

the accompanying illustration is attached to the carburetor in such manner that the exhaust taken from the exhaust manifold is passed around the chamber of the device. The generator itself is cylindrical in form.

It is stated that tests made with the device resulted in a great saving of gasoline, and that considerably more energy was developed by the motor. Similarly, it is claimed that the mileage a gallon was increased, it being 12.6 miles without the generator and 15.3 with the apparatus installed on a standard make of pleasure car.

Barrett Jack.

The Duff Manufacturing Company, maker of the Barrett automobile jacks, has brought out a new design, termed

the 1914. One of the qualities of the new jack is the casting integral with the malleable iron top, an adjustable lifting member, which is of advantage in that it permits using the jack where the height is less than the maximum of the regular top. The smaller top member slides and is secured by bolts. This construction adapts the jack to all types of machines.

The pawl points are machined all around, meshing perfectly, making for a large factor of safety, efficiency and convenience.

J. & B. Fuel Saver.

As the efficiency of the motor largely depends upon the correct proportions of fuel and air, a number of devices for regulating the supply of air from the

seat have made their appearance during the past year. The principle involved is that of admitting atmosphere when it is supposed that too large a quantity of

gasoline is emerging from the jet of the carburetor, and when the motor is attaining high speeds.

The majority of the devices marketed provide for manual control; that is, the operator of the car utilizes his judgment as to the amount of air required. The device manufactured by Jones & Buckoke, 1413 Michigan Avenue, Chicago, differs from conventional practise in that the air is admitted automatically and according to the speed of the engine.

The J. & B. automatic fuel saver is located on the dash and is connected by a flexible tube to the intake manifold between the carburetor and the cylinders. The dash device contains an air valve, which opens and closes according to the varying suction which changes with the speed of the engine.

When the motor is running slowly the valve is closed, but as the speed picks up, a valve member is automatically released from its seat, and allows air to be drawn into the intake manifold, the extra atmosphere being in proportion to the requirements of the engine.

No-Shammy Funnel.

The No-Shammy funnel is manufactured by the No-Shammy Products Company, Cleveland, O., and is marketed by Chas. E. Miller, 97-103 Reade Street, New York City. One of the qualities of the design is that the gasoline will flow as readily as through an ordinary funnel not equipped with a screen or filtering means. With the No-Shammy the fuel passes through quickly, while all water and foreign elements are trapped.

The principle of operation is the difference between the specific gravity of gasoline and water. When the fuel is poured into the funnel, any water and heavy sediment in it immediately settles to the bottom of the funnel, while the gasoline floats off through a gauze member. The particles of dirt held in suspension are prevented by the gauze from passing over.

It is pointed out that water can rise to the top of the funnel, as the film of gasoline over the gauze prevents it passing through. This is secured by scientific determination of the angles of the walls, position and mesh of the gauze, etc. The No-Shammy funnel is inexpensive, and sturdily constructed.

QUALITIES OF DIESEL OIL ENGINES.

IT IS held by many that the fuel problem would be largely overcome if the Diesel engine could be produced in small sizes suitable for service with the commercial vehicle, on account of the ability of this engine to utilize heavy grades of fuel. The advantages of the type are: The ability to use cheap and easily obtained fuels, economy of operation and the elimination of the carburetor and magneto. Some of the disadvantages of the Diesel engine are: High cylinder

Fig. 1—Sectional Diagram of Diesel Engine.

pressures necessitating great strength and weight, lack of flexibility, difficulty in starting and accurate measurement of the fuel.

Eric Walford, an English engineer, holds that the difficulties standing in the way of the development of the Diesel engine for commercial vehicles are mostly practical ones, and states that when the extraordinary advance that has been made in the construction of ordinary automobile motors is considered, the future seems hopeful. By the use of chrome and vanadium steels it would seem possible to make the parts of the required strength with comparatively low weight, rendering the engine practical for commercial vehicle use.

It is suggested that the pressure might be further lowered by heating the air so that the compression would not have to be so high to obtain the necessary ignition temperature. The lack of flexibility might be overcome by combining with the engine a simple form of electric transmission system, and the transmission itself might provide an electric starter.

The method of operation of the Diesel engine will be of interest to those not familiar with the design, and it will also serve to make clear the disadvantages as well as advantages above referred to. The drawing at Fig. 1 will be of service, but the illustration is merely diagrammatic, representing the chief essential features.

Operation of Diesel Engine.

It will be noted that the compression space is extremely small, and that, between the two main valves, the inlet and the exhaust, is arranged a fuel valve. Driven by the engine is a pump which supplies air to an air cylinder. The engine illustrated operates on the four-cycle principle, but the Diesel principle can be applied to two-stroke cycle engines also. It is assumed that the engine has exhausted gas through the exhaust valve in the ordinary way and that the piston is about to descend. The inlet valve in the cylinder head is then opened and air alone, usually at atmospheric pressure, is drawn into the cylinders. (Sometimes this air is at a pressure above that of the atmos-

phere.) On the upstroke of the piston this air is compressed until, at the top dead centre, the pressure is about 500 pounds to the square inch. (In the ordinary motor car gasoline engine the pressure rarely exceeds 75 pounds the square inch.)

At the top dead centre the central or fuel valve opens, admitting fuel and compressed air. Prior to this the space around the fuel valve has had supplied to it a small quantity of oil which forms the fuel. Directly the fuel valve opens, air, compressed to a pressure of more than 500 pounds a square inch, is admitted through the fuel space and the now open fuel valve, injecting the oil from the fuel space into the combustion chamber in the form of a spray.

Compression Temperature.

The air in the combustion chamber being at a pressure of about 500 pounds to the square inch, the consequent temperature is sufficient to produce ignition. The oil as it enters the combustion chamber therefore burns, and this combustion is maintained throughout a varying portion of the power stroke, say the first quarter, when the engine is running at full load. The supply of fuel and extra air is terminated by the closing of the fuel valve. The piston, therefore, descends under the pressure of the combustion above it, until towards the end of the stroke the exhaust valve opens as usual, and on the upstroke the products of combustion are exhausted. The same sequence is then repeated.

A small pump arranged at the side of the engine maintains the supply of compressed air necessary for injecting the fuel, and compressed air is also as a rule used for starting the engine, but the mechanism employed is omitted from the drawing to simplify it.

Fuels Available.

From the high temperature of the air in the combustion chamber it is clear that almost any finely divided fuel will be ignited. In addition to petroleum oils, creosote and tar oils can be obtained in practically any country, and it has been suggested that coal dust could be employed, and, theoretically, there is no doubt it could, but the practical difficulties are so great that experiments with this fuel have never proved a success. The fuels that can be utilized are all extremely cheap in themselves, and, furthermore, this engine does more work to a gallon

Fig. 2—Okill's Starting System for Diesel Engine.

never proved a success. The fuels that can be utilized are all extremely cheap in themselves, and, furthermore, this engine does more work to a gallon

of fuel than does the ordinary gasoline, kerosene or gas engine, so that the economy of running is still further increased. Carburetor and magneto troubles are non-existent, but in place of these there are the air pump and the air bottle.

Limiting Factors.

It will be readily understood that the pressures in the cylinders are extremely high, with the result that the cylinders and all moving parts must be correspondingly strong. This means great weight, and the weight of the reciprocating parts assists in limiting the speed of the engine, although there are more important limiting factors. Similarly, the engine will not run very slowly, so that the range of speed is very small. This certainly applied to the first gasoline engines, but everybody will agree that the modern automobile engine will operate at a sufficiently wide variation of speed, so that there is hope that the same improvement may be effected in the Diesel engine. To raise a compression of 500 pounds to the square inch it is clear that hand starting is impossible, but manual starting has been replaced on the motor car by the electric and other forms. However, considerably more power would be required to start a Diesel engine than an ordinary motor of the same size.

Starting Method.

The more recently patented arrangement shown at Fig. 2 is interesting as suggesting one method of overcoming this difficulty. Here the engine operates on the ordinary Diesel principle, but when the sleeve between the piston and cylinder walls is lowered, a port in the left hand side of it is brought opposite the combustion chamber, putting this in communication with a valve pocket. By this means the combustion space is considerably enlarged, so that the compression normally used on gasoline engines can be obtained. This valve pocket contains a spark plug and an inlet valve from which gas can be drawn from an ordinary gasoline carburetor. With the sleeve in the operating position the engine can work on the ordinary Otto cycle, using gasoline vapor. Directly it is well started the sleeve can be raised so as to cut off the valve pocket, allowing the engine to operate on the Diesel principle.

Varying Speed.

Accurate measurement of the fuel supply is of very great importance, and the power is varied by varying the period during which injection of the fuel occurs. The quantity of fuel supplied at each stroke is small even with comparatively large stationary engines. With an engine of four-inch bore and five-inch stroke, assuming the fuel pump to be five mm diameter, a stroke of only 3.1 mm would be required when the engine is running under full load, and under light loads the stroke would be only about three-quarters of a millimeter. This shows that the ordinary fuel feeding system would have to be considerably modified.

It is not suggested that attempts have not been made to use Diesel engines for motor car work, as Dr. Diesel himself co-operated with Sulzer Bros., Zurich,

in experimenting with a Diesel car, but without practical success. The work is now in the hands of the Delaunay-Belleville Company, in Paris, and before the late Dr. Diesel died he expressed great hopes for the future of his device in automobile development, and anticipated seeing a Diesel car in which all minor operations, such as gear changing, brake application, etc., were effected pneumatically. It is stated that this concern expects to have a car fitted with a Diesel engine on the road in the near future.

Factor of Fuel Supply.

As the pressures inside the cylinder are so extremely high, much difficulty is experienced in preventing leakage. This would be increasingly difficult in small engines in the hands of unskilled operators. The chief difficulty standing in the way of the adoption of the Diesel engine for motor car work is in measuring accurately the very small quantity of fuel required and varying the supply as the call for power varies. A variable delivery pump is an easy matter to design, but it is very difficult to make such a pump supply a minute quantity of liquid.

Fig. 3—Suggested Method of Fuel Feed for Diesel Engines Which Might Be Adapted to Automobiles.

The application of the Diesel engine to motor cars is dealt with at some length in a German magazine, *Allgemeine Automobil Zeitung*, of December, 1912. One method of overcoming the difficulty described therein is shown in Fig. 3, which depicts part of a cylinder head with a central fuel nozzle, which is of the open type. Just prior to the compression stroke the needle valve opens and a small quantity of fuel, under gravity or slight pressure, is caused to enter the open nozzle, the quantity admitted being determined by the period of opening of the needle valve. The nozzle contains perforated discs which impose a tortuous path on the fuel so that it does not enter the cylinder during the compression stroke. At the end of the compression stroke the air valve opens and compressed air scavenges the nozzle, blowing the finely divided fuel into the combustion chamber. In this case a single and comparatively large fuel pump for a number of cylinders is used, and the amount supplied is controlled by varying the movement of the needle of each cylinder.

MACHINERY, TOOLS, EQUIPMENT AND SUPPLIES.

LEAK-PROOF piston rings are marketed by the McQuay-Norris Manufacturing Company, St. Louis, Mo. The construction of these rings is a radical departure

Leak-Proof Piston Ring.

from conventional practise, as will be noted by an accompanying illustration being made in two pieces, and on the angle iron principle. Consequently there are no unsealed openings, as the flange of each section completely seals the opening of the other, thus obtaining the desired gas tight construction which makes for perfect compression.

They are made concentric instead of eccentric, and one of the qualities of the design is their equal tension on the cylinder walls. As the openings are diametrically opposite it is obvious that the tension is evenly distributed.

The Leak-Proof rings are in service in a large number of motors where trouble has been experienced by oil working up past the original members, and they are held to be decidedly efficient where imperfect compression has been experienced. The McQuay-Norris Company is issuing a booklet on piston rings, etc., which contains much valuable and instructive data upon the subject. The brochure will be mailed free upon addressing department D of the company.

BINKS ELECTRIC TIRE PUMP.

The Star Brass Works, 319 North Albany avenue, Chicago, is manufacturing the Binks electric tire pump shown in an accompanying illustration, and efficiency is one of its features. The equipment is most complete and includes suitable length of hose, flexible lamp cord, etc. The compressor is constructed of the best grade of iron, neatly enamelled. The cylinder has a bore of two inches and a stroke of five, and is bored and ground to exact dimensions. The piston rings are of

Binks Electric Tire Pump.

the same material as the cylinder and as carefully finished and fitted. All parts subject to friction are equipped with spring grease cups. The valves are of special design and material and, it is stated, will require no attention.

The compressor is operated by a .25

horsepower 110-volt direct or alternating current motor (60 cycles), and 15 feet of lamp cord with socket is included in equipment. Lubricant is prevented from reaching tires by a well designed oil extractor located between the pump and the hose. The relief valve may be set to any desired pressure, preventing over inflation or the bursting of tires. The outfit is mounted on a finished, painted platform two by 12 by 30 inches, and swivelling ball bearing casters make it an easy matter to move the equipment.

The Binks electric tire pump is constructed to withstand severe service and is liberally guaranteed by a maker having 14 years' experience in the production of pumps. Price lists and descriptive matter will be supplied upon request.

VICTOR ASSORTED GASKETS.

The Victor Manufacturing & Gasket Company, Troy and 21st street, Chicago, in addition to marketing its regular line of copper asbestos gaskets, is producing them in assorted sizes packed in boxes. Four different boxes are offered the trade. Box No. 1 contains 12 complete sets of gaskets for the Ford car, these comprising that for the cylinder head, intake and exhaust, etc. Box No. 2 contains 200 assorted copper asbestos gaskets selected from the most popular sizes universally used, and in proper proportion for everyday repairs on all makes of cars. The assortment is augmented by 65 selective sizes of gaskets to fit all makes of spark plugs marketed.

Victor Assorted Gaskets.

Box No. 3 has 50 assorted gaskets constructed especially for the intake and exhaust pipes and manifolds, exhaust flanges, carburetor connections, etc. There are 25 different sizes to choose from, making the equipment a valuable one to the repairman. Box No. 4 contains 100 assorted French type gaskets. All assortments are placed in a neat wooden box with steel hinge cover and the different sizes, etc., are located in compartments. Slips accompanying the boxes give the location and sizes. The trade prices will be forwarded upon request, also a catalogue.

MOSSBERG SOCKET BRACE.

The Frank Mossberg Company, Attleboro, Mass., is manufacturing the Mossberg socket brace No. 360, shown in an accompanying illustration. A brace is a

decidedly handy tool in the repair shop and service station and may be employed for a number of useful purposes, such as grinding in valves, removing the nuts of demountable rims, working about the power plant, etc.

The Mossberg brace is very efficient, being constructed of the finest grade of steel, dull nickel plated and with ebonized wood handle. It is 13 inches over all and is covered by the usual Mossberg guarantee. The chuck end of this brace holds all sizes of Mossberg sockets and those having a standard shank. The brace is moderately priced.

The company makes a specialty of pressed steel sockets, some of which are shown herewith. The product of the concern is well and favorably known among repairmen and the trade, as the sockets are constructed of pressed steel and hardened, and by their mottled finish. They fit hexagon and square nuts, set screws, and bolt heads. One of their qualities is that they are standard and will fit practically every socket set that is now on the market.

They are produced for U. S. standard hexagonal nuts and bolts, A. L. A. M. standard hexagonal nuts and screws, manufacturers' standard hexagonal head-

Mossberg Socket Brace No. 360.

ed bolts and for cap and coach screws. The maker calls special attention to the necessity when specifying, that dimensions of nuts should be given measured "across the flats", or, in other words, the smallest diameter of the nut or bolt head, and, unless the actual size of the socket is ordered, an allowance is made by the company of .03125 inch for clearance. The Mossberg sockets are marketed in attractive boxes, each containing one dozen. Prices and complete list of sizes will be mailed upon request. The catalogue issued by the company is most complete.

COWAN TRANSVEYOR.

The Cowan Truck Company, Holyoke, Mass., is manufacturing the Cowan transveyor, shown in an accompanying illustration, which is produced in four sizes, having capacities of 2000, 2500, 3000 and 3500 pounds respectively. One of the qualities of the truck is that it is an all-metal construction. It is designed to operate over rough floors, up and down inclines and with the platforms is held to save considerable time and labor in the transportation of material about the factory. It is pointed out by the maker that fully 75

per cent. can be saved in the ordinary factory equipment.

One of the features of the transveyor is its ample

Mossberg Pressed Steel Sockets and Container.

clearance when the platform is elevated, this being 2.75 inches. The type H transveyor is equipped with a specially designed hydraulic ram, and a few strokes of the handle will elevate maximum loads to a height of three inches, a clearance eliminating possibility of skids catching or encountering obstructions at the foot or top of inclines. It is stated that there is no possibility of the load being released until the operator presses a pedal, when the platform will slowly sink to the floor without shock or jar.

The front wheel of the all-steel construction is fully swivelled, making it possible to turn the machine in its length. The high grade ball bearings are protected by washers and dust caps, and the steering handle is at all times free, enabling the workman to guide the machine easily and accurately. The design of the handle is such that a straight pull is provided when removing the transveyor from beneath a platform. The wheels are six inches in diameter for the No. 1 and 2 types and seven for the others. The type H will be supplied with 10-inch wheels if desired. Special

Cowan Transveyor, Which Is Utilized with Special Platforms.

cifications, dimensions and prices will be forwarded upon request. John Cronin, 118 Pearl street, Boston, is agent for the Cowan Truck Company.

HINTS FOR PROPER MAINTENANCE.

THE removal and replacement of the pistons with their rings from a cylinder is not a troublesome task if the work is performed properly, but if the pis-

Utilizing Metal Band to Compress Ring When Piston Head Slipped into Combustion Chamber, Preventing Removal from Cylinder.

tons and rods are inserted in the cylinder before the latter is replaced on the crankcase, care should be taken to prevent the piston rings from expanding in the combustion chamber.

An instance of this kind was noted by the writer recently, and although the machine was a pleasure car, the method utilized to correct the trouble is applicable to commercial vehicle engines. The cylinders were cast in pairs, and a new unit had been ordered from the factory. Due either to carelessness at the factory or to the pistons moving in transit, both slipped upward until their heads came in contact with the top wall of the combustion chamber. Naturally, the top ring expanded and when an attempt was made to remove the pistons it was found that the ring had caught.

Owing to the limited space it was found impossible to insert any type of clamp to compress the ring, although several different methods and kinds of material were employed. The owner was advised by the foreman of a large garage to utilize piano wire, inserting it through the valve plug openings and passing it under and around the piston and ring. This method had been employed by the expert, who stated that sometimes it required considerable time to so locate the wire that it would compress the ring diametrically opposite the slot.

The owner, after repeated trials with the wire gave it up, as it was found that the wire either slipped when tightened or became lodged between the ring and the chamfer in the cylinder. The problem was finally solved as shown in an accompanying illustration. By making a thin strip of metal of approximately the same width as the piston ring and passing it through the valve plug openings, it was a simple matter to locate the band in the desired position; that is, diametrically opposite the slot. One person drew the band

taut and exerted an upward pull which forced the ring on its seat or groove in the piston. Another person utilized a pair of screw drivers, compressing the ring at the points indicated in the drawing. With the band and screw drivers, a three-point compressional effect was obtained, and it was a simple matter to withdraw the piston back into the cylinder proper. The other cylinder was treated in a like manner and the entire operation consumed but a few minutes. Before beginning the work the ring was turned so that the slot was on top, or between the screw driver points.

TIMING OVERHEAD VALVES.

The opening and closing of the various valves of an internal combustion engine have much to do with its balancing, and often excessive vibration of the power plant is due to a variance in the opening and closing points of the valves.

A method of timing the overhead or rocker type is suggested by a repairman, and it includes the disassembling of the motor and utilizing the crankshaft, flywheel and upper half of the crankcase. The last named is placed on a level surface and sufficiently high to clear the flywheel, as shown in an accompanying illustration. The crankshaft is then rotated until the crankthrows of the first and fourth cylinders are exactly on top dead centre. This position is obtained by means of a square held to the side of the crank web and a spirit level placed on the top of the blade. Having obtained this position, a pointer, constructed of a piece of tin, is placed on the centre of the crankcase as shown, and so located that its point will overlap the flywheel. A line is then scribed on the flywheel, which indicates top dead centre.

The flywheel is then rotated a half turn, or until the throws of the second and third cylinders are on top, and the exact vertical position is obtained by means of the square and the level. The flywheel is also marked. The cylinders are next replaced and the

Timing Motor with Overhead or Rocker Type Valves by Utilizing Crankthrows.

other parts of the motor are then reassembled.

The crankshaft is then rotated until the exhaust valve of the No. 1 cylinder closes. This should take

place shortly after dead centre. A chalk mark is then placed on the flywheel opposite the pointer, and the flywheel turned until the No. 4 exhaust closes, when the flywheel should again be marked where the pointer overlaps.

Any difference between the timing of the No. 1 and No. 4 markings, with relation to the pointer, can be altered by turning the camshaft backward or forward one or two teeth as required. The No. 1 and No. 4 intake valves are treated in a similar manner, and with a little adjustment of the tappets the intake valves referred to will fall in with the correct timing of the motor. The position of the valves should be taken both open and closed.

SPLICING CABLES.

If it becomes necessary to splice a high-tension cable, the wire of each section should be bared sufficiently to permit of making a good twist of the ends. The part is next soldered. As the high-tension current will take the path having the least resistance, the bare wire can be protected by covering it with some form of plastic tire cement, then wrapping the part with friction tape.

CARE OF MAGNETO TERMINALS.

To obtain maximum efficiency from the magneto its terminals and those of the transformer coil must be kept clean and tight. With the type of instrument providing dual ignition the battery current is carried to the breaker box, where it is interrupted by the breaker mechanism, although there are exceptions as in the Simms magneto for example.

If the leads to the breaker box are loose considerable trouble may be experienced in starting on the batteries. If oil or grease has accumulated around the terminals, remove the wire, etc., and clean with gasoline, noting if any of the strands of wire are loose. All wires should be soldered to the terminals and the latter so placed that there is no opportunity for them to come in contact with the metal of the breaker housing. The writer noted a case recently where a driver was delayed over two hours trying to start the motor. The trouble proved to be a defective connection at the breaker box.

DETERMINING STEEL.

A method of determining self-hardening steel from ordinary cast steel is to hold the metal against a high speed emery wheel. If the color of the spark given off be bright red, it can be taken for granted that the material being ground is cast steel. If it is a dull red, however, the steel is of the self-hardening brand, and the sparks made are very much like those given off from cast iron.

HYRAY-EXIDE LIGHTING PLANTS.

The Electric Storage Battery Company, Philadelphia, Penn., has begun the commercial production of what are designed as the "Hyray-Exide" battery and switchboard units for small electric lighting plants, with a view of meeting the requirements of those who are remote from central stations and wish to make their own light. The outfits are designed to utilize any available form of generating power and to create current, storing it in a battery, from which it is supplied to lamps as desired.

On a platform built on skids is constructed a tray in which the battery is placed, and in front of this tray is a low voltage switchboard, mounted on a standard. The legs of the stand for the switchboard are jointed, so that by releasing the two rear stay rods the board may be lowered to about 40 per cent. of its full height. The board is lowered for transportation.

The switchboard includes a generator switch and fuses, battery switch and fuses, an automatic cut-out and cut-in switch, a pilot light, and an ampere meter and an ampere-hour meter. To this a generator field rheostat may be added at the option of the purchaser. When charging is done while the battery is used for lighting a single-pole, double-throw switch is installed, this being necessary with either resistance cells in the lighting circuit or with the reduction of the number of cells during the charge. This switch is installed when desired.

The battery consists of 16 "Hyray-Exide" cells, these having a rating of 32 volts. These are supplied in three sizes of cell, the batteries being 44, 78 and 117 ampere-hours capacity. Beneath the switchboard is a sufficient space to locate a generator, and this can be operated by any power that is constant. A small gasoline or oil engine, or water power may be used. With the generator on the platform connection may be made with a belt and the plant is in readiness for use. These plants are particularly suited for garages, especially those where power is used during the day, which may be utilized for charging, and can be installed in small shops, residences, or wherever the battery can be charged. The plant is set up at the factory, aside from installing the generator, and with the battery and switchboard as a unit can be handled very quickly and conveniently.

The Dauch Manufacturing Company has been organized at Sandusky, O., by Daniel E. Storms, R. D. Mitchell, J. A. Giedeman and Charles Dick, with capital of \$800,000. The company has acquired the plant of the Sandusky Auto Parts & Motor Truck Company and will engage in the manufacture of power wagons and trucks.

At Jersey City, N. J., the Motor Tire Reconstruction Company has been incorporated by C. N. King, W. L. Steck and G. H. Russell, with capital of \$250,000, to engage in the production of motor vehicle tires.

CORRESPONDENCE WITH THE READER.

Timing Diagrams—J. W. E., Schenectady, N. Y.

Will you explain the use of motor timing diagrams? There is one in the book of instructions that came with our truck.

The timing diagram referred to is determined by the designer of the motor and the opening and closing points of the plan are such as to obtain the maximum energy of the motor. These diagrams are utilized by the workmen in the factory to set the valves when assembling the motor, and also to enable the repairman to set the valves correctly in the overhaul of the power plant.

Fig. 1—Timing Diagram.

The majority of manufacturers mark the periphery of the flywheel with steel stencil letters, and these are utilized with reference to an indicator or pointer attached to crankcase or some part of engine. If the valve timing is correct, that is, the same as when the motor left the factory, the opening and closing points, and centres, represented by the flywheel marks, will register with the pointer above referred to.

The flywheel of a motor timed according to the diagram shown at Fig. 1 would bear the following marks: 1-4 Up, 2-3 Up, 1-4 I-O, 1-4 I-C, 1-4 E-O, 1-4 E-C, 2-3 I-O, 2-3 I-C, 2-3 E-O, 2-3 E-C. The marks 1-4, or sometimes marked D-C or C, refer to positions of the pistons or crankthrows as being on top dead centre; I-O and I-C, the opening and closing points of the intake valves, and E-O and E-C, the opening and closing points of the exhaust members.

Referring once more to the diagram at Fig. 1, it will be seen that the circumference of the flywheel is laid off into degrees, also that the dead centres are indicated by a vertical line. With the diameter of the flywheel known it is a simple matter to figure out and lay off the degrees, but as this is generally done at the factory it will not be necessary in retiming valves of the average motor.

It will be noted that the inlet opens eight degrees after dead centre and this corresponds to the flywheel marks I-O 1 or 4. The intake remains open until the piston has completed the suction stroke and has begun the compression stroke, or the valve closes 38 degrees after lower dead centre. It will be noted that the valve remains open 210 degrees.

The exhaust valve opens 46 degrees below lower dead centre, remains open 241 degrees, and closes 15 degrees after top dead centre. If it be borne in mind that one complete revolution of the flywheel equals 360 degrees and that 180 represents the complete movement or stroke of a piston, the application of the

diagram will be more easily understood in respect to the opening and closing points of the valves.

To check the timing of valves on a motor that has seen considerable service, the flywheel is rotated in its usual direction until the mark 1-4 I-O registers with the pointer or indicator. In this position the intake valve of the first or fourth cylinder should start to lift. If not the tappet adjustment should be altered. The timing diagram is also useful when replacing an unmarked camshaft. The teeth of the latter are so meshed with the crankshaft gear that the cam of the intake valve of the No. 1 cylinder, for example, begins to lift the valve stem.

Dish of Wheels—E. J. K., Glenbrook, Conn.

Why is it that the front wheels of machines are closer together at the front and the bottom?

Some manufacturers dish the front wheels and toe them in at the front slightly. The amount of divergence from vertical is termed the camber and involves a mechanical principle—that the nearer to an alignment the centre of the spindle bolt and the pivot of the wheel are when turning, the easier the car will steer.

The gather of the wheels is to offset the effect of the camber, to make the tires wear more evenly, and also to prevent the wheels wobbling. This is obtained by bringing the extreme forward sections closer together, generally about .4375 inch, and the same method is employed as when noting the dish or camber.

These points are brought out in the illustration at Fig. 2. That at A shows the divergence from the vertical, and B a top view of the wheel, indicating the gather.

Vehicle Batteries—Interested, Waterbury, Conn.

Can you give information upon the capacity of electric vehicle batteries; that is, the mileage that can be obtained?

Fig. 2—Dish or Camber and Gather of Front Wheels: A, Showing the Divergence from the Vertical; B, Top View of Wheel, Illustrating Gather.

The subject was exhaustively treated in the February issue of MOTOR TRUCK under the head of Electric Vehicle Practise.

DOUBLE TAX LAW DEAD IN MICHIGAN.

The supreme court of Michigan has decided that the law providing for registration of motor vehicles in that state by horsepower, which eliminated the local taxation and would transfer from municipal to state revenue the amount paid by the motorists, has been declared unconstitutional by the supreme court of that state, and the new law being vitiated the assumption is that the old law will continue in force. This decision means that all amounts in excess of the old registration fee, which was \$3 a vehicle, must be returned to those who paid it.

The supreme court decides that while the law was entitled to a registration measure and assumedly was justified by the police power of the state, yet the sums specified were so much in excess of all necessary requirements that it could only be regarded as a means of providing a fund for a specific purpose; that is, the increase of the fee was to increase the fund to be raised, and instead of being a means for regulation it became a tax law. The opinion stated: "There can be no more labor or expense in registering a vehicle of high horsepower than in registering one of low power, and the only reasonable purpose in the graduated fee is the increased revenue. This graduated fee according to horsepower must be held to be a mere guise or subterfuge to obtain the increased revenue".

The law was tested by the supervisors of Wayne county on the ground that the tax that would go to that county under the old law, and this was a very large part of the entire revenue, would go to the state and would be used for highway construction in localities where it was not raised.

WORM DRIVEN AETNA TRUCK.

A worm and wheel driven truck of two tons capacity will be built by the Aetna Motor Truck Company, which has been organized at Detroit, Mich., with capital of \$150,000, \$50,000 of which is preferred and \$100,000 common stock. Of this amount \$113,800 has been subscribed, \$6800 paid in in cash and \$100,000 is in property. D. G. Wagner is president and William A. Eldred is secretary, and associated with them are Ernest A. Kinney, John J. Wilson and George Bumbert.

A building has been secured at Plymouth, Ind., by the Utility Motors Corporation of Chicago, and the machinery and equipment is being moved there preparatory to operating. The company produces gasoline engines for pleasure cars and trucks.

T. H. McGiehan, vice president and general manager of the Motz Tire & Rubber Company, Akron, O., underwent a successful operation for appendicitis April 18 at the Akron City Hospital, and is making a very satisfactory recovery.

RHODE ISLAND'S LIGHT LAW.

In Rhode Island after July 1 all vehicles using the roads at night must carry lights, the motor cars, wagons and trucks having the two white lamps visible from the front and a tail light, these to be displayed from an hour after sunset to an hour before sunrise, as prescribed by the law governing motor vehicle registration and operation, and all horse vehicles, save those carrying inflammable loads, must have a single lamp so displayed that it shall be visible from the front and the rear, and while no provision is made in the statute the expectation is that the lamp shall be mounted at the left side. This statute is identical with that recently enacted by the Massachusetts legislature.

The penalty for failure to comply with the provision as to lights shall be a fine to a maximum of \$20 for each offense, and in the event of a person so violating the statute refusing to give his or her correct name and address when requested by a policeman or constable a fine of \$5 may be imposed. With more than 13,000 motor cars and wagons registered in the state, and with the use of the highways by hundreds of others from out of the state each day, the universal lighting of vehicles will be a decided protection.

MARYLAND ELECTRIC TRUCK.

The Maryland Electric Vehicle & Manufacturing Company has been organized at Baltimore, Md., to build the Maryland electric wagons and trucks, and the purpose of the concern is to develop a series of sizes that will range in capacity from 1000 to 10,000 pounds. The machines will be offered at what may be regarded as moderate prices. The company is to build the batteries used in its machines and will guarantee these for 15 months, and parts necessary for replacement or repairs will be furnished to purchasers of the vehicles without charge for a year.

STUDYING TAP BREAKAGE.

At a meeting of the research division of the Society of Automobile Engineers, held April 21 at the headquarters of the organization at 1790 Broadway, New York City, one of the subjects considered was drill sizes. The breakage of taps was inquired into with a view of determining what methods might be developed to minimize the loss of these tools.

F. L. Metten, A. Cosgrove and A. Whartemby have incorporated as the Hercules Truck Manufacturing Company at Dover, Del., with capital of \$100,000, and will build motor wagons and trucks.

The Penn Spring Works has been incorporated at Baldwinsville, N. Y., with capital of \$25,000 by W. H. Robinson, F. C. Robinson and N. Hee, to manufacture motor truck springs.

S. A. E. EUROPEAN TOUR.

Will Visit Paris Salon and Olympia Show and Many Vehicle Factories.

The organization for the European invasion to be made by the Society of Automobile Engineers the coming autumn has been practically completed, and as now planned the Americans will pass two weeks on the steamers and 30 days in Continental Europe and England, being absent 44 days. This itinerary allows the tourists six days more than the tentative plan, two of which will be devoted to Paris and four to London, and the absence has been increased from 41 to 44 days.

Of the time that will be passed on foreign soil six days will be in Paris and 10 days in London, and the remainder will be given over to brief dashes into Italy, Switzerland, Germany and Belgium, with five days devoted to the journey from Switzerland down the valley of the Rhine and to stops in several cities for short periods.

The engineers will be received by different organizations where they will visit and they will have opportunity to see a great deal in the foreign factories, which will be thrown open to them. The proportions of the party are as yet unknown, but it is expected that it will number at least 75, and the total may reach 100. The plan comprehends departure from New York on Oct. 9, sailing on the Kronprinzessin Cecile of the North German Lloyd line. The party should arrive at Paris the evening of Oct. 15, and will remain there for six days. The Paris Salon will be opened Oct. 16, and this and visits to the different motor vehicle factories in the vicinage of that city will consume the time until Oct. 21, when the tourists will depart for Italy, where the next three succeeding days will be passed at Turin and Milan. Two days will be devoted to sightseeing in Switzerland, and then the trip down the Rhine will be begun, stopping at Schaffhausen, Stuttgart, Mayence, Cologne and Essen, and thence to Brussels, Antwerp, and thence by steamer to England, where London will be the objective point. The party will reach London the day of the opening of the Olympia show, and following visits to this the Americans will have opportunity to see many of the English motor car plants. The tourists will sail from Southampton Nov. 15, on the George Washington of the North German Lloyd line, and are expected to reach New York Nov. 22.

The itinerary as arranged is as follows:

- Oct. 9—Sail from New York.
- Oct. 15—Reach Paris. Headquarters, Edward VII. Hotel.
- Oct. 16-20—Visiting Paris show, and visits to the majority of the automobile and accessory factories in and around Paris.
- Oct. 21—Leave for Turin, Italy.
- Oct. 22—Turin. Arriving in morning, visiting factories and leave in evening.
- Oct. 23—Arrive at Milan and visit factories.
- Oct. 25—Leave Milan for Lucerne for sightseeing trip.
- Oct. 27—Leave Lucerne for Schaffhausen to visit factories.
- Oct. 28—Leave Schaffhausen for Stuttgart and visit factories.
- Oct. 29—Leave Stuttgart for Mayence.

- Oct. 31—Steamer trip on Rhine to Cologne.
- Nov. 1—In Cologne.
- Nov. 2—Short trip to Essen and return.
- Nov. 3—Leave Cologne for Brussels, Belgium.
- Nov. 4—In Brussels.
- Nov. 5—Leave Brussels for Antwerp and thence for London.
- Nov. 6-15—In London visiting Olympia show with side trips to many English factories.

WILL INSURE DEALERS' MACHINES.

The Manufacturers' & Dealers' Motor Underwriters is the name of a company incorporated under New York law by W. E. Metzger, E. H. Greenwood and W. B. Joyce, with capital of \$150,000, with W. E. Metzger as president, which will specialize the insurance of dealers' machines. The company has located its offices at 80 Maiden lane, New York City, and has begun business. H. A. Bonnell, who is widely known in the automobile industry and trade, resigned as assistant general manager of the National Automobile Chamber of Commerce to become secretary of the company. One form of insurance will be the issuance of short term policies by which machines can be insured by the dealers as soon as the sales have been made, a form of protection that has not been directly obtainable previously. Mr. Bonnell was formerly treasurer of the American Automobile Association, manager of the Automobile Board of Trade, and later with the National Chamber of Commerce.

CONVICTS TO MAKE BRICK FOR ROADS.

The New York legislature has appropriated \$50,000 for the construction of a plant at the state prison at Elmira for the production of brick, and it is proposed to use whatever can be turned out by the plant for the construction of state roads. The buildings will be erected and the machinery installed as quickly as practical, and it will be operated by convict labor. There is little probability that it will be in operation before late in the season, and the production will be but a very small part required for the road construction in the state.

The Hartford Auto Parts Company, Hartford, Conn., has increased the floor space occupied by its factory at the Colt armory to 32,000 square feet and has recently added to its force of workers, the increase being necessary to meet the demand for universal joints and cone clutches, which are its principal products.

The Gould Storage Battery Company has leased a building at 1761 East 18th street, Cleveland, O., and will open a branch and service station in that city as soon as the equipment and supplies can be installed.

The Federal Motor Truck Company, Detroit, Mich., has appointed R. P. Spencer, formerly with the Paeschke & Frey Company, its sales and advertising manager.

THE A B C OF MOTOR TRUCK IGNITION.

Part XXI--Construction and Operation of Connecticut Igniter System Including a Combined Igniter and Distributer and Ingenious Automatic Switch--Employs Dry Cells or Storage Batteries as a Source of Current Supply.

By C. P. Shattuck.

SYNCHRONIZATION of the spark, or the invincible recurrence of a spark at the same point in the piston's travel, is a subject that is receiving careful consideration by ignition specialists, and during the last two years experiments and tests have proved the direct bearing of flame propagation on motor efficiency.

To obtain the maximum output of a motor the mixture must be as completely burned as possible, or in other words, the greatest energy is secured when the explosion occurs at a fixed point in the piston's travel. Some authorities hold that there is only one such point irrespective of speed and that all advancing

or retarding of the spark control is made to secure the explosion at that time.

It has been explained that with all high-tension ignition systems it is necessary to break or interrupt the primary circuit. Before the explosion takes place there are several factors to be considered. These are: The time consumed in mechanically accomplishing the break, the question of induction

Fig. 131—The Connecticut Igniter Assembled.

lapse or the difference in time between the break in the primary circuit and the occurrence of the high-tension spark, and the rapidity of the flame propagation.

Time a Factor.

One maker of ignition apparatus holds that while the time factor in any of the above instances on slow speeds may seem inconsequential, it is important, because when a motor is turning at 2000 revolutions a minute, it means that it is turning at 33.33 revolutions a second or through 12,000 degrees a second. Or in other words, it is turning through 12 degrees every one thousandth of a second. From this it will be seen that time consumed to accomplish an explosion

is an important factor as the speed of the motor increases.

This time factor is referred to as "lag" and is effective in that degree in which it is variable. Up to that point where flame propagation starts, this "lag" when variable is a synchronism or lack of synchronism.

The elimination of this "lag" is more or less complete according to the method employed in interrupting or breaking the primary current. The position of the advance lever is also a factor. It will thus be seen that either mechanical or electrical "lag" in an ignition system of the high-tension type is an undesirable factor, especially where the speed of the piston is variable as in motor car practise.

The factors above discussed are held to be eliminated in the Connecticut automatic igniter, manufactured by the Connecticut Telephone & Electric Company, Meriden, Conn., which is well known in the automobile industry as a maker of ignition systems. The company, which has had a wide experience in building commutators, induction coils, distributors, magnetos, etc., holds that its igniter system includes all the advantages of preceding forms, and is free from the limitations to which each has been subject. It is also held that mechanical and electrical "lag" have been eliminated; that is, that there is no discoverable interval between the interruption of the primary current and the occurrence of the spark at the plug.

Fig. 132—Igniter with Distributor Cap Removed.

Fig. 133—Dust Cover Removed from Igniter to Show Breaker and Cam.

The system presents many interesting features, but in the main includes principles indorsed by sound electrical engineering practise. The interruption of

Fig. 134—Showing Igniter Used with E and G Systems Completely Disassembled.

the primary current is by a breaker box similar to conventional magneto design, and the low-tension current is built up or transformed by a coil. The source of current supply may be either dry cells or a storage battery, and the system is particularly adapted to vehicles utilizing a generator for charging the battery.

Novel Automatic Switch.

The most noticeable feature of the equipment is the automatic switch. With certain ignition systems if the switch lever be left on "Battery" the cells will become exhausted because of a closed circuit. For example: With the timer and induction coil type of ignition, it is possible for the motor to stop with the crankshaft in such position that the primary circuit would be closed and failure of the operator to move the switch lever to the "Off" position would rapidly exhaust the current supply. This is prevented in the Connecticut system, as the current is cut off automatically.

The combined igniter and distributor is shown at Fig. 131 and resembles a conventional distributor in appearance, but its operation differs considerably. It is very compact, as will be noted by the dimensions given in the diagram at Fig. 138. That for a four-cylinder motor is slightly over four inches high and 2.75 wide, these figures being overall dimensions. The

Fig. 135—Type E Combined Coil and Switch with Cover Removed to Show Terminal Connections—Note the Enclosed Spark Gap.

igniter is mounted on a vertical shaft running at half engine speed irrespective of number of cylinders. Primary circuit is interrupted and the high-tension current distributed in the same unit, and one of its qualities is its simplicity. Emphasis is laid upon the accessibility of the components and the impossibility of their assembly other than correctly. The timer and distributor as-

sembled is shown at Fig. 131. Fig. 132 depicts the distributor cap displaced, while Fig. 134 shows the apparatus completely disassembled.

A single spark is produced upon a break occurring in the primary circuit which through being closed energizes a coil, and the break is effected in the igniter by means of a cam revolving against a breaker arm. Referring to Fig. 134, also Fig. 133, it will be seen that a shaft is employed, having four longitudinal ribs, equidistant, these acting as lifters for the breaker lever.

The breaker lever is practically half a circle, with one end pivotally mounted, while at the other end is a platinum contact point. The last named member makes contact with a fixed platinum point, and, being of ample size, it is stated that it requires no attention whatsoever.

A hardened and ground steel roller is mounted on the lever member and when one of the shaft ribs or cams comes in contact with it, the lever is moved outward, separating the platinum points, actuating these much in the same manner as magneto points. The breaker arm is well insulated from the base, and it is stated that no engine ground is necessary in the primary circuit, as its winding is insulated from the secondary ground in the coil. The advantage of the design emphasized is that there is no possibility of the ignition system being affected through any short circuiting of any other electrical circuit, such as a lighting system for example.

Fig. 136—The Automatic Switch—Removing Three Cover Screws Exposes All Working Parts.

Retention of Parts.

A cap or cover is fitted, carrying at its centre a bearing for the extended shaft; a dowel in the timer case, entering a hole in the cover, makes it impossible to replace it other than correctly. A mica window is incorporated over the contact points, permitting of noting their operation while running. The cover is retained by a split pin above it. A spring washer constructed of two small saucer shaped steel members, put together with concave sides facing inwardly, maintains the proper tension, and an anti-friction washer is interposed between the spring washer and the top of the timer cover.

The distributor consists of a central cylinder of insulating material impervious to heat, moisture or lubricants, and is carried at the top of the shaft, which is cut away where it enters the rotor and fits into a

hole of corresponding shape, thus obtaining a drive. This arrangement absolutely prevents improper assembling. Located in the periphery of the rotor is a radial carbon distributing brush, which is pressed outwardly by a light spring in a recess of the rotor. Connection or passage of the secondary current is by means of a light, flat steel spring on top of the rotor.

The same insulating material as is used in the rotor is employed for the distributor housing, and imbedded in its inner walls are the contacts, these being two, three, four, six or eight, according to the type of the igniter and the number of cylinders to be fired. The contacts are connected to terminals which may be either horizontal or vertical as desired.

Ingenious Switch.

The switch shown at Fig. 136 is most ingenious. It will be seen that it is provided with three buttons. One is for the battery and another for the magneto, in

Fig. 137—Rear View of Type G Automatic Switch, Showing Method of Making Connections.

case a dual system is utilized, or for two sets of batteries. The third button is a releasing member, which automatically throws out any button pushed in, thereby cutting off the current supply. There is ample room between the

buttons, permitting their operation by the hand or foot, and the construction is rugged.

The plungers on which the buttons are mounted operate through holes in a plate inside the cover plate; the perforated plate is pivoted and a spring keeps it normally pressed in one direction. When a switch button is pressed the conically shaped end of the plunger slightly swings the plate, which then snaps into a notch under the cone, holding the button down and keeping the circuit closed. When the releasing button is pressed its cone actuates the plate sufficiently to slip it out of the notch in the switch button that has been in engagement, allowing it to move upward.

Mounted on the swinging plate is a sliding bar, the ends of which reach the cones of the button plungers. The length of the plate is such that when one

button is pressed, the cone moves it out of the way, that is, towards the cone of the opposite button, and the plunger can be depressed all the way. If, however, both are pressed at the same time, both are blocked by the sliding plate, which is too long to allow both to go down together.

The automatic switch referred to, which throws out the switch disconnecting the battery in the event the operator of the car fails to do so, consists of a vibrator of the electric ball type, the hammer of which strikes the edge of the plate referred to in the description of the switch, pushing it out of the plunger notch. The current operating the vibrator is cut in by a thermostat, a mechanism that has been employed for many years in the Connecticut telephone switches. The thermostat, when heated by a continuous and abnormal flow of current, establishes a contact, and the vibrator becomes active, operating the switch, which is released in a fraction of a second, cutting off the current supply. Upon the thermostat cooling, which requires but little time, it returns to its normal position.

It is stated that the time required for the thermostat is controllable by a regulating screw. Ordinarily it is so adjusted that if the timer is short circuited when the driver closes the switch to start the engine, 30 seconds will elapse before the switch is automatically thrown out, allowing sufficient time to start to crank the motor.

Fig. 138—Diagram Giving Dimensions of Combined Igniter and Distributor.

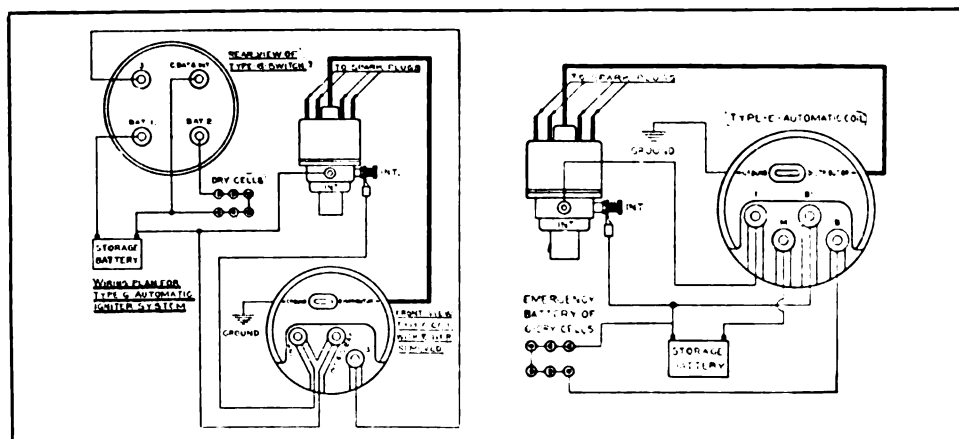

Fig. 139—Firing Plans of Connecticut System: At Left, Plan for Type G or GJ; at Right, for Type E or EJ.

Two types of igniters are produced, S and J. The former is used with the type E and G systems and is supported on the shaft through two high grade an-

nular ball bearings. Self-lubricating bearings are utilized with the type J igniter, these comprising a substance formed by mixing graphite and babbitt when the metal is in a molten state. The mixture is subjected to an enormous pressure, and bushings made of it run without lubrication.

Two types of coils are employed, E and G, and the former is shown at Fig. 135. It is of the flush dash type, and extreme care has been taken in the design of the connections, and to make the case impervious to heat, etc. It will be noted that a spark gap is incorporated to protect the secondary windings from damage in case a plug terminal becomes disconnected. The gap is enclosed in a glass tube, is easily observed, and is not accessible to fuel vapor. All terminals on the coils and switches are of the self-locking spring type, and all igniters are constructed for attachment to a .5-inch shaft, and are locked by two set screws.

It is stated that the igniter produces its hottest spark on the slowest motor speeds, and that it increases as the speed decreases, although the spark is much more than ordinarily intense at high speeds. This makes possible easy starting and throttling the motor to very low speeds without sacrificing efficiency, as the propagation of the flame is very rapid.

Laboratory tests of the Connecticut system are interesting. It has been demonstrated that it eliminates electrical "lag"; that is to say, there is no discoverable interval between the interruption of the primary current and the occurrence of the spark at the plug. It is stated that this holds true at all speeds.

Advantages of System.

It is claimed that the system operating with a fixed spark is productive of more electrical energy than a magneto manually controlled. According to charts there is a remarkable absence of electrical lag. The company believes that with a system free from lag only two positions are necessary, one for safety as when starting, and one for running. It is held that mechanical lag has been overcome in the timer, as the lifting cam acts directly on the breaker arm; that springs, etc., are eliminated, and that the action is not affected by centrifugal force.

The wiring plans for the type G and GJ systems, also for E or EJ, are shown at Fig. 139. If emergency dry cells are not used with the first named system the lead to battery post No. 2 is eliminated. The post B in the E or EJ system is not wired when cells are dispensed with.

A bulletin on "Automobiles in Hong Kong and Southern Cuba" has been issued by the bureau of foreign and domestic commerce of the Department of Commerce and Labor, Washington, D. C., which may be obtained by application to the bureau.

A branch office and sales department is to be established at Atlanta, Ga., by the Maccarr Truck Company of Scranton, Penn.

SEARLE TUBE TESTED.

A test was made in New York City April 14 of the Searle unburstable tire tubes, which are designed for use with any form of pneumatic tires. The tubes are claimed to be particularly enduring in any form of casing, no matter how much worn, and the makers maintain that patches, shoes, sleeves, etc., are not necessary to obtain from them satisfactory efficiency.

The test was made with 13 taxicabs, all fitted with two tire cases so badly worn as to be regarded as useless, which were driven from the Hotel Astor to Garden City and return. In several instances the cases were ruptured for several inches, and to insure complete test some of them were cut to have holes two inches diameter close to the bead. The taxicabs were used because a greater number of discarded shoes were obtainable, and more machines were available than might be obtained from other sources.

The only tube to fail was cut by a piece of glass bottle where it was unprotected by the casing, but aside from this the tubes endured all that was claimed they would. The Searle tube is to be manufactured and sold in this country under patent rights granted by the Searle Unburstable Inner Tube Company, Ltd., of Birmingham, England.

NET PROFITS \$1,115,609.

Gross profits of \$1,880,654 and net profits of \$1,115,609 are shown in the annual report of the Indian Refining Company for 1913, and the statement is made that this ought to be considerably increased in 1914 from the fact that a vigorous selling campaign has been inaugurated. Because of litigation involving the trade mark of the company, which has been decided favorably to a continuance of the use of "Havoline" on all its products, the company was not as aggressive in its methods during the pendency of the legal controversy, and for this reason the financial results were not as large as might have been had there not been a period of practically "marking time".

UNITED STATES RUBBER DIVIDENDS.

A quarterly dividend of two per cent. on the first preferred stock, of 1.5 per cent. on the second preferred stock and of 1.5 on the common stock has been paid by the United States Rubber Company to stockholders of record at 3 in the afternoon of April 15, payable without closing the transfer books on April 30. The United States Tire Company is a subsidiary of this concern.

Recently appointed agencies for Koehler delivery wagons are W. A. Cookerly, Macon, Ga.; A. E. Lewis, Kansas City, Mo.; Snyder & Winks, New Tripoli, Penn.; S. Sedgwick & Sons, Knoxville, Tenn., and R. S. Blaisdell, York Village, Me.

TIME-SAVING TIRE SERVICE STATIONS.

THE knowledge that a rubber tire is vulnerable, and may be damaged or ruined despite the greatest care, and the material cost of renewal, causes the owners of machines used for freight transportation much reason for serious reflection. Were a rubber tire to be expected to yield service such as may be anticipated from metal, the problem would be greatly simplified. There are instances of extreme mileage being obtained from tires that are carefully used, but the experience has been with the majority, at least, that the service has not been up to the guarantee.

The tire that will give the guaranteed mileage is regarded as being full value for the cost, and if for any reason the guarantee is not realized the owner must bear some expense. But in addition to this there is the actual loss from the period the machine is not serviceable pending renewal or repair. The withdrawal of a vehicle from use for a part or all of a day may not represent in actual cash a sum of importance, but the losses of time from this and other causes may in the aggregate represent a considerable period during the service of a machine, and there is also the possibility of business being affected because of the uncertainty or dissatisfaction of those who are served.

The majority of service power vehicles is today fitted with tires that are assumedly quickly removable.

There is, however, a considerable proportion that has the old type of equipment, in which the tires must be installed with special tools. There are services for which the pressed-on type of rim is regarded as superior to the easily removable forms. With small capacity wagons, especially when speed is desirable, pneumatic tires are used, and these are generally with quick removable rims. Pneumatic shoes are more susceptible to damage than are the solid forms, but they may be changed or a temporary repair made with hand tools under almost any circumstances. Spare tires and tubes may be carried and reasonable provision made for average exigencies.

But handling truck tires is a different proposition. Spares are rarely, if ever, carried, and changes cannot be readily made because of the weight of the shoes and rims, while chain hoists are the only practical manner of handling wheels, which are extremely heavy. The tires, if the machine is of capacity of two tons or more, are generally of two types, single and dual bands, and if spares were carried it would be necessary to provide one of each, and the weight would be of sufficient proportions to consider it. As solid tires may be used if considerably damaged, extra shoes are seldom considered, and another reason for not providing them is the large cost for equip-

Equipment and Resources of the Goodrich Service Station in New York City: No. 1, the Battery of Drill Presses in Use; No. 2, Hydraulic Presses for Removing and Installing Tires; No. 3, Removing Band from Heater in Blacksmith Shop for Installation on a Wheel; No. 4, 30-Foot Elevator That Serves as an Entrance to the Garage; No. 5, Section of the 75 by 90-Foot Tire Stockroom.

ment that deteriorates with lapse of time, no matter whether it is carried or not. Because of the limitations of the guarantees the tires are not often bought until they are wanted for use.

There are other factors that are worthy of consideration in connection with tire use. The fewer the changes the better, and the less the number of occasions for loss of time, but not even the largest public service station has the special equipment necessary for quickly handling the shoes. Generally the protection in a large private garage is limited to spare wheels on which tires are installed, and this means a change of wheels instead of the shoes, the policy being to send the wheels to a service station of a tire manufacturer.

But this applies to the owner of a number of machines, and not to the man who has several, so that with those who do not have spare wheels the best protection is an extra tire or two, but here comes in very effectually the item of investment and the question whether or not the spare tires and the possibility of loss on guaranteed service will offset the time that will be saved by the truck. This variable is extreme and cannot be estimated. For this reason many truck owners are inclined to purchase tires only as they are needed, and in many instances the wheels are sent to service stations or to branches of manufacturers for the removal of the old shoes and the installation of the new.

From the viewpoint of the tire user the time that must elapse from the giving of an order to the delivery, or for making a change on a wheel, is a factor of great importance. While there is no reason to believe that retail tire dealers can do more than supply shoes from stock, the fact remains that the owners of machines expect that they be protected so far as this is possible or practical. Tire manufacturing plants are concentrated for economic reasons, and yet to meet the demand for what is regarded as service the larger concerns have been impelled to establish stations wherever the volume of business has reached sufficient proportions to justify them.

The stations are usually located where the transportation facilities are such that the surrounding area can be well served, for those sending wheels or tires must depend upon freight or express service. The stations must be stocked with sufficient numbers of the different types and sizes, and there must be such equipment that whatever work is necessary can be quickly done. There is expectation that business will be influenced by the stations.

The service stations are by no means small establishments. Generally a warehouse is connected, from which distribution of stock can be made, and the other departments include a garage, where vehicles can be stored while work is progressing, a repair shop with facilities for every requirement, and machinery for removing and installing the tires on the wheels. The machine equipment of some stations is such that they are in every respect complete factories, for every char-

acter of work is done. Not only this, the stations must be in charge of an expert, who has available men trained in all departments, skilled in handling tires and work in connection with them, and day and night forces are often frequent because of machines being brought in for tire changes between the regular working hours.

The establishment of such stations means in each instance the investment of a considerable amount of money, the perfection of an organization, and the development of service that will satisfy patrons, and naturally they can be located only in a comparatively small number of cities.

The policy of the large tire manufacturers is to establish these stations as rapidly as conditions will justify. Pleasure car shoes can be handled at the stations and distributed from the warehouses, and some tire makers who have abandoned retail sales have equipped their warehouses with additional facilities to meet the demands. The advantage of the stations to the owner of the service wagon or truck cannot be over-estimated, for this means a diminution of time losses, and as the business is developed the facilities and resources can be improved.

One of the most interesting examples of tire service stations is that maintained by the B. F. Goodrich Company in New York City, which is of large proportions and is equipped for every work. The accompanying series of illustrations is of especial interest, as it shows the facilities provided to meet the requirements of tire users. The stockroom is 75 by 90 feet and in this is kept a large supply of shoes. A small elevator is used to carry the tires to the lower rooms. The work shop includes a blacksmith department, where the rims are removed from and placed on the wheels, and these are heated and expanded or cooled and contracted as necessary, the heating being done on large circular beds by blocks heated by gas. The beds are covered with metal shields that retain the heat and concentrate it. One view shows a heater with the crew about to remove a band for application to a wheel. Another illustrates a battery of drill presses, which are used for adapting and fitting bands for the application of the shoes. For the removal or installation of the bands large hydraulic presses are used, and these ponderous machines can be handled like the most delicate mechanism by the workmen, so that exact adjustment may be made. An idea of the size of the garage may be obtained from the fact that it has three entrances, one of which is through an elevator with a platform 30 feet in length, which is probably the largest in New York City. The other entrances are at either side of the floor, so that turning and shifting is minimized when a machine is once located. In work of any kind the delay is extremely short, and so far as the station is concerned it is practically in readiness to take on any kind of restoration or change and give the same satisfaction that would be expected from the main factory.

MILLER'S BIG 1914 CATALOGUE.

The catalogue issued for 1914 by Chas. E. Miller, 97-103 Reade street, New York City, specified as No. 28, is the largest publication yet issued by Mr. Miller, consisting of 248 pages and a cover, and it is entirely devoted to description and illustration of standard and special lines included in the stocks of the main store, or the branches in New York City and Brooklyn, Buffalo, N. Y.; Boston, Springfield, Mass.; Hartford, Conn.; Detroit, Mich.; Cleveland, O.; Philadelphia, Penn.; Atlanta, Ga.; Newark, N. J., and New Orleans, La. Mr. Miller claims to be the largest automobile supply house in America, and as he is manufacturer, jobber, importer and exporter, full lines are carried at all the stores for the benefit of the trade.

The circulation of the catalogue is 100,000, those distributed abroad being sent by freight to ports of entry and mailed by brokers, the duty being 15 per cent. The size of this edition may be judged from the fact that the white paper as received from the mill would make a strip five feet in width from New York to Washington; the pages laid end to end would make a band 7.5 inches width 1925 miles in length; the printing surface of the pages has an area of 13,721,525 square feet; piled flat the catalogues would reach skyward 2000 feet above the combined heights of the Metropolitan, Singer and Park Row buildings, three of the highest structures in the Metropolis; that 50 one-ton automobile trucks were necessary to make delivery to the postoffice for mailing. The catalogue is a reference book for manufacturers, jobbers, dealers, owners, etc., and is mailed to any person at request.

HIGH REGISTRATION TAX KILLED.

The organized endeavors of the Automobile Club of Maryland, with the assistance of interested owners and those engaged in the industry and trade, were effectual in opposing the bills pending in the legislature of that state that comprehended large increases in the registration tax. That relating to pleasure vehicles provided for a \$50 tax for a motor of 10 horsepower with graduated increase up to \$200 for motors of 40 or more horsepower, and that applying to freight wagons and trucks increased the tax from a flat rate of \$3 to a graduated scale with a maximum rate of \$65. The bills providing that all vehicles should carry lights at night and for better traffic regulations also failed of passage. The state will receive the benefit of \$6,600,000 which was appropriated for the construction of good roads.

BOTTLER'S DELIVERY WAGON.**Double-Decked Platform Body Installed on Palmer-Moore Chassis.**

The Palmer-Moore Company, Syracuse, N. Y., builder of Palmer-Moore delivery wagons, has produced a body that is designed for the special use of the Zenith City Bottling Works of Duluth, Minn., that has been installed upon a 1600-pound chassis. The bottles are carried in crates or racks, and while these may be stacked, for the purpose of facilitating handling, separation of the racks into tiers, although this requires more space and somewhat increases the height of the load, is regarded as desirable.

The wagon is manned by a driver, and that he may have the fullest opportunity to reach his customers and visit prospective patrons, as well as cover a large route, the loading and unloading of crates of filled and empty bottles must necessarily be minimized, for a considerable patronage is dependent upon the activity of the driver. Stacking the crates would mean handling them over several times, as well as a loss of time.

The body consists of two decks, each 90 inches length and 66 inches width, with a slight rail at the sides and ends to prevent the load shifting from movement of the machine. The upper deck is two feet above the lower and is supported by four corner and two side stanchions, tied by bolted angle straps, the construction being light, but very strong. The two decks have a total area of 82.5 square feet. With this form of body the crates can be handled from either side and the rear, or from the front or the running boards equally well, and the full freight can be carried so placed that no changing is necessary. The body affords every desired convenience with marked simplicity. In the event of storm the body and load may be covered by a tarpaulin that gives every protection.

Double Deck Open Body Fitted to a Palmer-Moore Delivery Wagon for the Service of the Zenith City Bottling Works, Duluth, Minn.

DELIVERS ROYALTY'S ORDERS.

Willys Utility Wagon in the Service of Baker at Heidelberg, Germany.

The German people are generally believed to be devoted to all creations of the realm of Kaiser Wilhelm—so much so that they prefer their own productions to those of other nations—and there is every reason to believe that the Germans are highly skilled as mechanics. But apparently they have not produced what will, for the price, equal American creations, this opinion being based on the attitude of Emil Roesler, a baker and confectioner of Heidelberg, the seat of the great university and one of the numerous palaces of the Emperor. One would believe that national pride and the prestige that use of domestic products would be assumed to establish would have influenced this man's choice of a delivery wagon, because his prominence in the community is such that his equipment is observed and commented on, but instead of selecting a German or even European vehicle, he purchased a Willys Utility machine, built by the Willys-Overland Company, Toledo, O.

The chassis is American from springhorns to the end of the chassis frame, but it is equipped with a full panel body that was designed for the particular purpose for which it is used—the delivery of bakery products and confectionery in the city and vicinity. In general appearance, however, the body differs very little from the standard equipment, and might escape special observation were it not for the fact that on the sides are three separate coats of arms, these being in effect notification to the public that the owner has official appointment to serve different royal families, the principal one being the Grand Duke of Baden. The machine visits the palace several times daily and delivers the Prince's bread, pastry and sweets, and in-

centidentally serves others of minor consequence.

The fact most patent is that the owner made a choice that he believed would be the most satisfactory for his investment, and that he preferred an American vehicle, which has not been frowned upon or regarded as discrediting German industries by his royal patrons.

VALUE OF TIRE SECTION.

An example of the economy of using motor vehicle tires of sufficient size was effectually demonstrated by the Factory Oil Company, Akron, O., which is operating a 3000-pound White machine. The initial equipment was 38 by 4.5-inch shoes, which were removed at the expiration of six months. The tires were replaced with 39 by 5.5-inch shoes, which were driven for a year, covering more than 15,000 miles.

AUTOMATIC IGNITION COMPANY.

Garry E. Wayman, S. A. Braden and E. J. Stehick, all of Pittsburg, Penn., have incorporated the Automatic Ignition Company, with capital of \$600,000, which is to locate in Pittsburg and manufacture spark plugs and different forms of ignition system components adapted for all kinds of motor vehicles and internal combustion engine installations.

MYSTERY OF THE PALMER-MOORE.

The Palmer-Moore Company, Syracuse, N. Y., has a mystery to deal with in that it recently sold a delivery wagon to the Cia, Transcontinental de Petroleo, Tampico, Mexico, which was shipped from the factory with the expectation that it was to be transferred to a steamer sailing April 17 for Tampico. The consignee is one of the largest concerns engaged in producing and refining petroleum in that section of Mexico, and it had bought the machine to use it as a patrol wagon, the purpose being to assign a crew of guards to it and carry the men to such parts of the company's property as conditions might necessitate. Whether the wagon will eventually reach its destination, or will be seized and pressed into the service of the American forces is the mystery, and with the conditions as they now are in Mexico there is some probability that it will not be quickly solved. The builder says it will do good service no matter who possesses it, and hopes a report of it will be received.

Willys Utility Delivery Wagon Used by Emil Roesler, Baker and Confectioner, of Heidelberg, Germany, to Serve Royalty and Other Patrons.

NEW ENGLAND CONVENTION OF THE E. V. A.

THE success of the promotion campaign of the Electric Vehicle Association of America is through the activity and the enthusiastic co-operation of the members, and of all the divisions of the organization there is none as consistently persistent as the New England section. This body is made up of the members of the Electric Motor Car Club of Boston and individuals associated with various electrical interests throughout the New England states.

The second annual convention of the electric vehicle interests of New England, which has been organized by the New England section, will take place at the Engineers' Club, Arlington and Newbury streets, Boston, beginning Tuesday, May 19, and will continue two days. There will be three business sessions but these will be preceded by the May meeting of the New England section, which will take place Monday evening, so that practically three days will be given over to the activities of the electric vehicle interests.

The May meeting of the New England section will take place at the American House, Hanover street, Boston, beginning at 6:30 the evening of May 18, and there will be a dinner. Invitations have been extended to members of the Boston Chamber of Commerce and officials of the different railroad and steamship lines affording service to Boston in particular and New England in general, and there is reason to expect a very large attendance of men of prominence in all manner of transportation enterprises. The principal speaker of the evening will be Fred A. Hortter, car accountant of the Boston & Maine railroad system, whose subject will be "The Effect of the Motor Truck on Terminal Freight Congestion", which will be specifically applied to Boston and vicinity, dealing with the conditions that can be best realized by those who have to meet them. Following the address there will be discussion and there will be consideration of the influence of the different bodies and the possibilities for improvement.

The first session of the convention will take place the afternoon of May 19, beginning at 1, the registration taking up the greater part of the morning. The second and third sessions will take place Tuesday evening and Wednesday morning. The programme will include the following papers:

"Co-Operation", by W. H. Blood, Jr., former president of the Electric Vehicle Association, associated with Stone & Webster of Boston, Mass.

"Recognition of the Electric", by Hayden Eames, president of the Standard Electric Company, Detroit, Mich.

"The Electric Vehicle Association of America", by A. Jackson Marshall, executive secretary of the Electric Vehicle Association of America, New York City.

"Garaging and Service", by J. C. Bartlett, president of the Bartlett Garage, Philadelphia, Penn.

"Competition—Fair and Unfair", by A. Vere Shaw of the Peerless Motor Car Company, Boston, Mass.

"What Constitutes a Good Electric", by A. C. Fach of the Rauch & Lang Carriage Company, Cleveland, O.

"Utility of the Electric Vehicle, Pleasure and Commercial", by E. J. Bartlett of the Baker Motor Vehicle Company, Cleveland, O.

"Weak Links in Electric Truck Salesmanship", by E. Nelson Carle, advertising manager of the General Vehicle Company, Long Island City, N. Y.

"The Relative Fields of Electric, Gasoline and Horse Trucks", by H. F. Thomson, instructor of the Electric Engineering Department of the Massachusetts Institute of Technology, Boston, Mass.

"Touring by Electric Automobiles", by J. S. Codman, treasurer of S. R. Bailey & Co., Boston, Mass.

In connection with the convention will be an open business forum which will be conducted by Converse D. Marsh of New York City.

Following the afternoon session Tuesday there will be a visit of the delegates to the splendid garage and service station of the Edison Electric Illuminating Company of Boston in Massachusetts avenue, Boston, which is the largest and most carefully equipped station in the world. The visitors will be shown about and the equipment exhibited and demonstrated and a beefsteak dinner will be partaken of. The evening session of the convention will be held at the service station.

The concluding session of the convention will be held the following morning at the Engineers' Club, and at its conclusion the delegates will proceed to Bass Point, Nahant, where an outing and sports will be enjoyed, and a dinner will be served at the Bass Point House in the evening, at which there will be brief speeches. The arrangements for the convention have been made by a committee of which Charles H. Miles is chairman. An attendance of several hundred is anticipated and visitors are expected from all parts of the East.

The creditors of the defunct Grabowsky Power Wagon Company have received a third dividend of five per cent., making a total thus far paid by the trustee of 35 per cent., in addition to the 20 per cent. paid by the creditors' committee, or 55 per cent. in all. Another dividend is expected.

The Chicago sales office of the United States Light & Heating Company of Niagara Falls, N. Y., has been removed from 1013 People's Gas building to 2335 State street, this being a consolidation of the sales and service departments.

UNDERWRITERS ADJUST INSURANCE RATES.

New Schedule for Western and Southeastern Departments, but That Applying to Eastern Section Continued with Revision of Non-Valued Form of Policy.

THE insurance rates for the entire country were considered, amended and adjusted by the Automobile Underwriters' Conference at its meeting in New York City, April 10, the purpose being to make the rates uniform in the different departments, the country for the purpose of motor vehicle insurance being divided into departments, to which specific classification and rates are applied. In the general application of insurance policies to motor vehicles there is no distinction made between pleasure and freight or service machines, and for this reason the schedules determined do not make separate rates for the two classes.

One of the most important results determined was that the dealers in western, southwestern and southeastern states cannot insure vehicles in their possession against theft or fire at the rates charged for pleasure car insurance, even where short rate cancellation is provided for.

The conference adopted new schedules for the Western department, which includes the states of Ohio, Indiana, Illinois, Michigan, Wisconsin, Minnesota, Iowa, Kansas, Nebraska, North Dakota, South Dakota, Wyoming, Colorado and New Mexico and for the Southeastern department, which is made up of Virginia, North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, Arkansas and Oklahoma and these were made effective April 20.

A schedule that was adopted about a year ago for the New England and Middle department, including the Metropolitan district, was continued with the revision of the non-valued form of policy.

By reference to the following schedules one will note that provision is made for a reduction in premium amounting to 15 per cent, if the vehicle insured is equipped with a fire extinguisher such as is approved by the Underwriters' Laboratories of the National Board of Underwriters, and the extinguisher is constantly carried on the machine. This provision was added to the policies last autumn after it had been established by the Automobile Insurance Company of Hartford, a company not having membership in the Automobile Underwriters' Conference, and no extinguisher of the pump type of quart capacity has been approved by the laboratories save that made by the Pyrene Manufacturing Company, New York City.

The value of the new rates as established is principally to the insurance companies, as this eliminates the need of varying records and simplifies the office work, while it affords protection at a given figure with reference to any department. These details are of no consequence to the owners of insurable vehicles, for

the least price obtainable is the main desideratum, but business equity demands that the protection given be the same throughout the country wherever conditions are at parity. This is the nearest to national uniformity in rates ever adopted by the underwriters.

The new schedules are the following:

WESTERN AUTOMOBILE SCHEDULE.

On gasoline power driven private pleasure motor cars and commercial vehicles, such as trucks, delivery wagons, based on manufacturers' original list prices:

	Class A.	Class B.	Class C.
Limits of amount of insurance include equipment, but not additional bodies. See additional equipment and additional bodies rules below.....	\$3500 and over	\$1500 to \$3599	\$700 to \$1499
This and Next Year Models—Insure for not to exceed actual cost or less than 50% of original list price	1½%	1¾%	2%
Last Year Models—Class A, amount of insurance at option of company; Class B, not more than 70% of original list price; Class C, not more than 60% of original list price	1½%	2%	3%
Year Before Last Models—Class A, amount of insurance at option of company; Class B, not more than			

CLASS No. 1

AMOUNT FOR INSURANCE Including Equipment But Not Extra Bodies Subject to "Instructions and Limits"	Original List Price of Automobile, when New (Not Second Hand), Excluding Cost of Additional Equipment and Extra Bodies												
	4500 and Up	3500 to 6499	4500 to 5499	3500 to 4499	3000 to 3499	2500 to 2999	2000 to 2499	1500 to 1999	1000 to 1499	700 to 999	500 to 699	300 to 499	200 to 299

500 to 599							4 1/4	4 1/4	4 1/4	3 1/4	3 1/4	3 1/4	3 1/4
400 to 499								4 1/4	4 1/4	4 1/4	4 1/4	4 1/4	4 1/4

All cars listed at less than \$700 take a rate of 3 1/4 %, irrespective of the amount insured, but the minimum premium for full form of policy shall be \$12.50, or with theft and valued policy classes eliminated, the minimum premium shall be \$10.00.

Second Section of Rate Card Which Is in Force in the Eastern States.

ditional rate must be charged. Pro rata cancellation allowed with a minimum charge of \$1.

SOUTHEASTERN AUTO SCHEDULE.

Rates for the full form of policy, gasoline pleasure and commercial type cars:

	Class		
	A.	B.	C.
Original list price of automobiles when new, excluding cost of additional equipment and extra bodies	\$3500 and over	\$1500 to \$3499	\$1499 and less
This and Next Year Models—Insure for not more than actual cost.....	2 1/2 %	2 1/2 %	2 1/4 %
Last Year Models—Insure Class A for not more than 80%, Class B for not more than 60% and Class C for not more than 50% of list price	2 1/2 %	3 %	3 %
Year Before Last Models—Insure Class A for not more than 70%, Class B for not more than 50% and Class C for not more than 40% of list price.....	3 %	3 1/4 %	3 1/2 %
Three-Year-Old Models—Insure Class A for not more than 60%, Class B for not more than 30% and Class C for not more than 20% of list price	3 1/4 %	4 %	5 %
Note—Second-hand cars, charge 1/2 per cent. in addition to above rates.			
Electric Cars—Models of all years, 2 per cent.; second-hand cars, charge 1/2 per cent. in addition to above rate. Maximum insurable amounts at the option of underwriter.			

Taxicabs, Livery and Renting Automobiles—All risks of this kind must be submitted to the home office. If approved, will be written at not less than 1 per cent. in addition to schedule rates, subject to the following indorsement:

"In consideration of \$..... additional premium, permission is hereby granted for the automobile herein insured to be used for carrying passengers for a compensation, provided it is under the personal supervision and guidance of the assured or a chauffeur in his employ while being so used".

Rates for the Restricted Form of Policy.

(The theft and reinstatement features excluded from the full policy by attaching the indorsement provided for that purpose.)

Electric Automobiles, Taxicabs, Livery and Renting Automobiles, Gasoline Pleasure and Commercial Automobiles—A reduction of 1/2 per cent. allowed from the rates for the full form of policy.

Minimum Premium.

For the full form of policy.....	\$12.50
For the restricted form of policy.....	10.00

Dealers' Automobiles.

Rates for full form of policy:

New gasoline cars—	
Listing for \$3500 and over.....	2 1/4 %
Listing for \$1500 to \$3499.....	3 %
Listing for \$1499 and less.....	3 1/4 %
New electric automobiles, all models.....	2 %
New steam automobiles, all models.....	3 1/4 %
(Subject to 1 1/4 % reduction if boiler and burner are located in front of dashboard.)	

For second-hand and rented cars charge 1 per cent. in addition to above rates. Pro rata cancellation allowed with a minimum charge of \$1 except on cars listing for \$1499 and less the minimum charge is 50c. Amounts of insurance at option of underwriter.

Rates for the Restricted Form of Policy—A reduction of 1/4 per cent. is allowed from the above dealers' rate for the elimination from the full policy of the theft and reinstatement features. Minimum premiums same as above.

Fire Extinguishing Devices—A reduction of 15 per cent. of the premium is allowed if a device approved by the Underwriters' Laboratories of the National Board of Fire Underwriters is carried on the automobile and an indorsement provided for that purpose is attached to the policy. This reduction, however, is not allowed on additional premiums for the theft full coverage, collision sustained and property damage.

European Privilege—At an additional rate of 1 1/2 per cent. policies may be extended to cover a European trip under the form of indorsements provided for that purpose. If the risk of the transatlantic trip, going and returning, be eliminated, this privilege can be granted without extra charge.

SCHEDULE FOR EASTERN STATES.

The schedule for the eastern states, which applies to New England and the Middle department, including the Metropolitan district, is shown in detail in the accompanying charts. In connection with these it should be stated that all gasoline vehicles are for the purpose of rating divided into two general classes. In No. 1 class the rates included in the columns A, B, C and D apply to machines of last year, this year and next year's production; the rates stated in columns E, F, G and H apply to machines of this year and next year's production; the rates specified in columns J, K, L and M apply to machines of this year and next year's production, and the special provision for rate for those listed at less than \$700 value, applies to machines of this year and next year's production. The No. 1 classification rates shall apply to machines in the hands of the original owners.

No. 2 class includes all machines not included in No. 1 class.

The other specifications of the schedule are as follows:

Instructions and Limits.

Amounts to be insured must not be more than actual value and be limited as follows: Columns A, B, C and D, cars of this year and next year models for not less than 50% of original list price. Columns E, F, G and H, cars of this year and next year models for not less than 50% of original list price; cars of last year models for not more than 80% of original list price; cars of year before last models for not more than 60% of original list price; no policy on cars of models earlier than the above shall be issued for an amount in excess of 40% of original list price. Columns J, K, L and M, cars of this year and next year models for not less than 50% of original list price; cars of last year models for not more than 70% of the original list price; cars of year before last models for not more than 50% of original list price; no policy on cars of models earlier than the above shall be issued for an amount in excess of 40% of original price.

Additional Equipment.

In addition to the amounts fixed by these limits, additional equipment may be insured for not exceeding \$300 on cars in columns A to H inclusive, and \$200 on any other cars by means of the following form of indorsement:

"In consideration of an additional premium of \$....., the sum insured under this policy is increased by \$..... to cover the value of additional equipment not furnished with the car by the manufacturer at its list price; all other terms and conditions remaining unchanged".

Additional premium for this additional amount shall be charged for at the same rate as charged in the body of the policy. The rate on the policy to be computed without reference to this rider.

Electric Automobiles.

Rate for all models 1½%. A reduction of ¼ of 1% for the elimination of theft and valued policy clauses is permitted using the indorsement provided for that purpose. Amount of insurance at discretion of company.

Steam Automobiles.

Cars of this year and next year models, rate not less than 3%. Cars of last year models, rate not less than 3½%. A reduction of ¼ of 1% is permitted if boiler and burner are located in front of dashboard. A reduction of ¼ of 1% is permitted for the elimination of theft and valued policy clauses using the indorsement provided for that purpose. Amount of insurance at discretion of company.

Livery and Renting Automobiles.

All applications covering cars used for livery and for renting purposes must be submitted to this office. If approved they will be written subject to the following clause, not less than 1% additional being charged:

"In consideration of \$..... additional premium permission is hereby granted for the automobile herein insured to be used for carrying passengers for a compensation, provided it is under the personal supervision and guidance of the insured or a chauffeur in his employ while being so used".

Additional Bodies.

In determining the original list price of automobiles having more than one body, the sum of the cost of the chassis and the higher priced body shall be taken as the original list price and the amount of insurance for the purpose of arriving at the rate to be charged shall be the amount insured on the chassis and the higher priced body. No change to be made in the classification of the car during the policy period.

In the case of an automobile equipped with an extra body or bodies, a specific amount must be applied to the chassis and equipment and to each body, the same rate being charged on the extra body or bodies as is charged on the automobile. The following clause to be used:

"In consideration of an additional premium of \$..... on and after date this policy shall cover an additional amount of \$....., which shall apply only on extra body used in connection with the automobile insured hereunder, and the insurance on the chassis and original body shall be divided as follows: \$..... on chassis and equipment; \$..... on extra body".

All other terms and conditions of this policy remaining unchanged.

Dealers' Automobiles.

On new gasoline cars charge 2¼% in columns A to D; 2½% in columns E to H, and 2¾% for all others.

On new electric cars charge 2% for all models.

On new steam cars charge 3¼% for all models, except where boiler and burner are located in front of dashboard, where a rate of 3% shall apply.

On all second-hand cars 1% additional rate must be charged.

Pro rata cancellation allowed with a minimum charge of \$1, except that the minimum charge on new cars listed at less than \$1500 shall be 50c.

Amounts insured at option of underwriters.

Note—Automobiles in the hands of dealers may be written under the ordinary form of policy at rates provided for private pleasure cars subject to cancellation on a short rate basis only, except pro rata cancellation may be allowed when a new policy is issued on the same car.

A reduction of ¼ of 1% will be allowed for the elimination of theft and valued policy clauses, but in all cases the minimum charge of \$1 and 50c shall apply as above indicated.

Commercial Automobiles.

Shall be written for amounts, and at the scheduled rates, as provided for private pleasure automobiles.

Second-Hand Cars.

Cars in hands of other than the original purchaser of the car when new shall in no case be insured for an amount in excess of the cost of the same to the insured.

REVISED NON-VALUED RATES.

The schedule of rates for non-valued form of policy, excluding theft and reinstatement clauses, applying to New England, the Middle department and the Metropolitan district, as revised, and applied April 20, is as follows:

Gasoline Pleasure Cars.

	Per Cent.
Cars of this and next year models—	
Insured for not less than 80% of list price.....	1½
Cars of last year models—	
Listing \$3500 and over.....	1½
Listing \$1500 to \$3499, insured for not exceeding 80% of list price.....	1½
Listing under \$1500, insured for not exceeding 70% of list price.....	2
Cars of year before last models—	
Listing \$3500 and over.....	2
Listing \$1500 to \$3499, insured for not exceeding 60% of list price.....	2½
Listing under \$1500, insured for not exceeding 50% of list price.....	2½
Cars of models three years old—	
Listing \$3500 and over.....	3
Listing \$1500 to \$3499, insured for not exceeding 40% of list price.....	3
Listing under \$1500, insured for not exceeding 40% of list price.....	3½
Four-year-old models and older—	
Minimum rate, insured for not exceeding 40% of list price	4½

Electric Cars.

All models	1½
------------------	----

Commercial Trucks.

Of not less than one ton capacity—	
This and next year models.....	1½
Cars rented, leased or used for carrying passengers for compensation—charge 1% in addition to above rates.	
Minimum premium, \$5.	

CREDITORS DIRECT BUSINESS.

The business of the Standard Roller Bearing Company, Philadelphia, Penn., is now controlled by a committee of five representing the creditors, the members being Joseph Wayne, Jr., William C. Potter, Herbert DuPuy, James P. Lee and Charles T. Taylor; this form of administration being recommended by the receivers. The committee has been authorized to carry on the business until May 1, 1915, and, if necessary, to continue for a period of not more than six months following that date. The company has an indebtedness of approximately \$1,500,000, this being to bond holders, banks and general creditors in proportions of about a third each. The quick assets are appraised at \$792,000 and the assets at \$1,831,432.

SECRETARY KELLY ENTERTAINS.

At the Union Club, Cleveland, O., on May 6, George H. Kelly, secretary of the Baker Motor Vehicle Company, entertained a group of men well known to the electrical and electric vehicle interests of the country. The guest was Frank W. Smith, president of the Electric Vehicle Association of America, who was visiting the Baker factory. Following his visit to the factory Mr. Smith inspected the garage and station of the Delivery Company in East 22nd street, which uses a considerable number of electric trucks and wagons, and the Baker City Sales electric garage, which is claimed to be one of the largest and best equipped garages of the world, his attention being especially directed to the equipment. Mr. Kelly's other guests were S. E. Doane of the National Electric Light Association, Manager L. P. Sawyer of the Buckeye Lamp Company, President C. L. F. Wieber of the Rauch & Lang Carriage Company, General Manager George L. Milner of Erner Electric Company, Commercial Agent Mathias Turner of the Cleveland Illuminating Company, Commercial Manager T. P. Cagwin of the Cleveland Telephone Company, Manager H. B. Gay of the Cleveland office of the Electric Storage Battery Company, District Sales Agent George D. Smith of the General Vehicle Company, Manager Ayers of the truck department of the General Motors Company and President Hayden Eames of the Standard Electric Car Manufacturing Company.

TRACTION COMPANY OPENS GARAGE.

A building owned by the Wilmington & Philadelphia Traction Company at Wilmington, Del., has been converted into a garage for electric machines, and the company proposes to maintain a public service station as a part of its business. The structure was originally the main power plant of the company, which operates a street railway system, but later on was given over to boosting the current distributed to the trolley wires in the city. With the improvement of the facilities of the company the building was not useful and to make it productive and to give impetus to the use of electric vehicles, the garage was decided on. The greater part of the business expected is from the owners of wagons and trucks, although pleasure cars will be garaged. The company operates a trolley and telephone system at Chester, Penn.

"UPLIFTING" STATE ROADS.**Governor Dunne Inaugurates Campaign to Improve Illinois Highway.**

Governor Edward F. Dunne was the most active citizen of Illinois April 15, which day was named by him by proclamation for all public-spirited citizens to unite in working on the highways and inaugurate a campaign intended to "pull Illinois out of the mud". It was a strenuous occasion for thousands who responded to the call, for throughout the state individuals and organizations of all kinds began an attack that was primarily a reduction of the ruts by dragging and the filling and evening of the surfaces, for obviously without careful experience and tools and good supervision permanent improvement could not be made.

The enthusiasm of the citizens in some of the communities ran high and a great deal of practical work was done, but the real purpose was to direct the attention of the people to the conditions that existed and to demonstrate to them that systematic betterment would bring about material benefit and economy of transportation. Governor Dunne, accompanied by men interested in educating the people to the advantages of improved roads, officials of motoring organizations, state and county and local officials, and men prominently identified in commercial and industrial enterprises, drove from early morning until late in the evening through different communities. He made a score of speeches in advocacy of the construction and substantial maintenance of good roads, and he took part in at least a dozen undertakings.

One of the events of the day was at Mooseheart, where the industrial farm of the Loyal Order of Moose is located, where he turned the first spade of

Governor Dunne of Illinois Addressing the Citizens of Mooseheart, Ill., from a White Tractor Constructed for Road Building in Kane County.

earth on a new road, and made a speech from a White tractor. The machine is a truck specially built for construction work, being geared low, having very wide tired wheels, and fitted with a dumping body. It may be used for hauling trailers or operated as a unit, and will serve for spreading and rolling material, as well as pulling drags, plows and graders. With the wide steel tire equipment it may be driven on very soft ground, where animals would not have footing. The statement is made that one tractor has done the work for which 30 mules were required and that the saving through its use was approximately \$700 a month.

S. A. E. RESEARCH COMMITTEES.

The Metropolitan section of the Society of Automobile Engineers has organized a number of research committees which will make special investigations and will make general report, some to be reflected by conclusions of the committees instead of individuals. The committees have been chosen with a view of obtaining special information on subjects which promise to be productive of extremely beneficial results. The committees are:

Gas-electric vehicles, David Beecroft, chairman; William P. Kennedy and Lars G. Nilson. Kerosene carburetors, A. B. Browne, chairman; W. Rautenstrauch, Joseph Tracy and Roger B. Whitman. Greases, H. M. Martin, chairman; George K. Bradfield, W. R. Parish and L. P. Prossen. Non-electric continuous torque transmission, L. M. Dieterich, chairman; Morris R. Machol and John R. Cautley. Engine characteristics, James L. Breese, chairman; Lloyd A. Busby, Robert McA. Lloyd, Finley R. Porter and W. M. Power. Governors, Arthur J. Slade, chairman; C. W. Fletcher and H. G. McComb.

VACUUM OIL COMPANY'S REPORT.

During the year 1913 the Vacuum Oil Company, Rochester, N. Y., which has capital of \$15,000,000, did a business approximately 25 per cent. in excess of that of the previous year. The total assets of the company as of Dec. 31, were \$34,484,184.33, and there was a surplus of \$17,151,049.46, in addition to which was \$100,840.44 reserved for insurance. The net profit was \$3,375,373.53, to which must be added the profits from stock in foreign companies that netted \$1,457,156.18. Dividends of three per cent. were declared in April and October. The company will pay another three per cent. dividend this month.

Walter L. Mitchell, who has been associated with the Packard and International Motor Company's branches at Boston, has been made manager of the branch that has been established in that city by the United States Mill Supply Company of Providence, R. I., agent for the Mais line of trucks.

FOREIGN TRADE CONVENTION.

May 27-28 at Washington, D. C., will take place a convention for the discussion of the possibilities of American foreign trade, organized by the American Manufacturers' Export Association, the American Asiatic Association and the Pan-American Society, and based on a realization that exportation is now at a point where its future is vital to the country's prosperity. Other nations have systematic foreign trade policies, but the united export business has been developed chiefly through the abundance of natural products and the individual enterprise of manufacturers. In the volume of foreign commerce England is first, Germany second and the United States third. The general committee is headed by Lloyd C. Griscom, former ambassador to Italy and Japan.

Many commercial bodies will be represented as well as railroads and industrial enterprises. Secretary Redfield of the Department of Commerce will open the convention, and there will be papers by Fairfax Harrison, president of the Southern Railway; H. G. Hergert, president of the Illinois Manufacturers' Association; E. C. Simmons of St. Louis, Mo.; E. N. Hurley, vice president of the Illinois Manufacturers' Association; Alba B. Johnson of Philadelphia, president of the Baldwin Locomotive Works, and James A. Farrell, president of the United States Steel Corporation, and others, who will speak on vitally important subjects.

MAKING SERVICE AGENCIES.

W. H. Riblet, eastern representative of the Service Motor Truck Company, Wabash, Ind., is now making agencies for his company in New England and has thus far met with excellent results. He expects to have the Service machines, which are of 3000, 4000, 6000 and 8000 pounds capacity, strongly established in this section. The Service Motor Truck Company is now in its fifth year and because of the conservative policy followed it has expanded its activities comparatively slowly, and has until now not had agents east of New York City. The Service trucks are well and favorably known and are constructed of the products of the standard manufacturers of the industry, and besides the resources of the company those of the makers of parts are at the command of the users.

The Pull-More Motor Truck Company has been incorporated at Detroit, Mich., by Frank C. Krueger, Henry M. Marks, Ralph S. Moore and Marvin A. Smith, with capital of \$250,000. The company will engage in the manufacture of Pull-More tractors.

T. H. McGiehan, vice president and general manager of the Motz Tire & Rubber Company, Akron, O., has sufficiently recovered from an operation for appendicitis as to be at his desk for a few hours each day.

EXPORT TRADE OPPORTUNITIES.

Manufacturers or selling agents of motor trucks who are interested in the development of foreign or export trade will be interested in the desire of a firm of motor car engineers, that already represents one make of American vehicle, to increase its business. This concern wishes to secure catalogues and other detail information of trucks, from which a choice will

View Showing the Front of the New Plant of the Weed Chain Tire Grip Company at Bridgeport, Conn.

be made. Another concern wishes to purchase several machines of from 15 to 20 horsepower with bodies suited for the haulage of case petroleum, petrol and the like, and desires to make a selection from catalogues, which should be accompanied by prices and terms of selling. These may be addressed as file numbers 12,559 and 12,715 respectively at the bureau of foreign and domestic commerce, Washington, D. C., or the branch offices of the bureau—315 Custom House, New York City; 629 Federal building, Chicago; Association of Commerce building, New Orleans, La.; 76 Appraisers' Stores building, San Francisco, Cal.

GALION COMPANY REORGANIZED.

The plant and assets of the Cleveland-Galion Motor Truck Company, Galion, O. which were recently sold by a receiver, and purchased by several citizens of Galion, have passed into possession of the Galion Dynamic Motor Truck Company, which has been incorporated with authorized capital of \$250,000, \$100,000 of which will be preferred stock. The plan originated by W. J. Geer for the issuance and distribution of the stock has been approved by the Ohio Utilities Commission. The company was incorporated by John M. Delbig, Harry B. Greig, John J. Bittner, J. B. Holmes, Charles Shaef-er, N. G. Knight and G. W. Nichols.

The American Carbon & Battery Company has been incorporated at Chicago, Ill., with capital of \$250,000, by W. C. Schramm, H. J. Wrape and H. Wrape.

NEW WEED CHAIN PLANT.**Company Established Its Offices at the Big Factory at Bridgeport, Conn.**

The Weed Chain Tire Grip Company, which for a number of years maintained its executive offices at 28 Moore street, New York City, has removed its headquarters to Bridgeport, Conn., where the big factory of the company is now in operation, and where it should be addressed in the future. The demand for the chains produced for all classes of motor vehicles has been such that to keep pace with it additional facilities were necessary, and the result was the construction of the plant especially for its requirements.

The buildings are of the most approved types for manufacturing purposes and have been equipped with machinery that will produce the chains with the largest degree of economy. The capacity of the plant may be judged from the fact that it will produce 60 miles of chain daily for motor vehicle use when worked to full productiveness, but there is abundant opportunity for expansion if there should be need of greater facilities. A railroad siding from the New Haven railroad makes possible the receipt of materials and shipment of products in very large quantities and eliminates handling, greatly reducing the cost of distribution, for Weed chains are sent all over the world. The plant is constructed to have an attractive appearance and compares very favorably with the most prominent manufactories of Bridgeport.

The Liggett Spring & Axle Company has removed its plant from Cleveland, O., to Monongahela, Penn. J. H. Newhart, treasurer of the company, has become general manager, following the resignation of H. R. McMann as vice president and general manager.

Rear View of the Weed Chain Tire Grip Company's New Factory, Showing the Railroad Siding and Shipping Facilities.

KNOX SALE CONFIRMED.

The sale of the real estate, machinery, merchandise, material and other property of the Knox Automobile Company, which was made provisionally by the trustee in bankruptcy, has been confirmed by the court and the plant has passed to the possession of E. O. Sutton. The statement is made that it is Mr. Sutton's purpose to continue the manufacture of pleasure cars, tractors and fire apparatus, and the company is now disposing of the pleasure cars and trucks on hand preparatory to bringing out the new products. The factory has been systematized and plans made for enlarging the production with the most approved manufacturing methods. The intention is to make the Knox Automobile Company one of the strongest concerns of the kind of the East.

DIXON STOCKHOLDERS UNANIMOUS.

The stockholders of the Joseph Dixon Crucible Company at a meeting at Jersey City, N. J., April 20, cast 9628 votes of a possible 10,000, and unanimously re-elected as directors George T. Smith, William Murray, George E. Long, Edward L. Young, William G. Bumsted, J. H. Schermerhorn and Harry Dailey. The officers of the company, president, George T. Smith; vice president, George E. Long; treasurer, J. H. Schermerhorn; secretary, Harry Dailey, and assistant treasurer and assistant secretary, Albert Norris, were also re-elected.

BUILDING DELIVERY WAGONS.

The first of a type of light motor delivery wagon is now being constructed by Robert G. Howard at a Boston shop, which will be placed in the market at a moderate price. Mr. Howard was for a considerable period manager of the Vulcan-Bessemer Motor Truck Company, Boston, Mass., and is well known throughout New England. The wagon will be of conventional design, having a 22.5 horsepower, four-cylinder, water-cooled motor, and the capacity will be 1500 pounds. The drive will be by shaft.

CREATES MOTOR CAR SERVICE.

The volume of business of the Pyrene Manufacturing Company in motor vehicle equipment has necessitated the creation of a department that will specialize the protection of cars, wagons and trucks, and this has been placed in charge of C. Lewis Allen, formerly New York City manager for the Service Recorder Company. The Pyrene Manufacturing Company makes and markets fire extinguishers and its headquarters are at 1358 Broadway, New York City. The resources of this new department will be at the command of vehicle owners who desire information of any kind relative to insurance protection, and will be free to all inquirers.

GRAMM-BERNSTEIN EXPANSION.

The plant of the Gramm-Bernstein Company, Lima, O., which is now inadequate for the business, is to be increased in size considerably during the present year. Work will shortly be begun on a steel and concrete structure, 110 by 48 feet, which will be used for assembling and painting, and other buildings will be erected during the spring and summer. The demand for B. A. Gramm's trucks, which are produced by this concern, has been increasing steadily and the prospects for the year are regarded as extremely bright.

GMC FACTORY IMPROVED.

The plant of the General Motors Truck Company, Pontiac, Mich., has been considerably improved by rearrangement of the different departments, changes that are expected to better facilitate the work. Much attention has been directed toward fire protection, concrete floors being installed, and a 100,000-gallon reservoir has been constructed, this being a reserve in the event of failure of the supply of city water, and in addition to the sprinkler system throughout the buildings.

MILLER NOW SELLS TRAILERS.

The sales of the patent trailers developed by the Troy Wagon Works, Troy, O., have been placed in the charge of A. R. Miller, who was for a considerable length of time engaged in sale of ball bearings and is well known in the industry. The Troy trailers have been specially developed for use with motor trucks and tractors and are constructed with capacity up to five tons. The manufacturer has found sufficient interest manifested in tractors and trailers to justify the establishment of this special department of the business.

PALMER-MOORE FOR LOZIER COMPANY.

The Lozier Motor Company, Detroit, Mich., has received delivery of a Palmer-Moore delivery wagon, fitted with an open express body, which will be used in carrying materials and supplies between the factory and the shipping terminals, as well as general transfer work about the city. The truck is fitted with a water-cooled engine and a sliding gear transmission gearset. The choice made is regarded by the Palmer-Moore Company as expert recognition of the high class qualities that are claimed for the machines it produces.

H. E. A. Raabe presented a paper on "Carburetors", which was illustrated by a projectograph, at the monthly meeting of the American Society of Engineer Draftsmen, at the Pulitzer building, New York City, the evening of April 17.

MOTOR VEHICLE EXPORTS.

During the eight months ending with February, 1914, the total value of automobiles, motor trucks, motorcycles, engines, tires and parts exported was \$23,337,332, and during the same period the value of all other vehicles exclusive of steam locomotives, was \$12,529,844. For the eight-month periods ending with February, 1912, 1913 and 1914, the exports included respectively 12,347 motor vehicles, valued at \$12,000,000, 14,488 valued at \$14,852,000 and 16,883 valued at \$15,716,000, and during the same periods the imports were 717 motor vehicles valued at \$1,572,000, 569 valued at \$1,329,000 and 230 valued at \$529,000. In March 2479 automobiles were exported from New York, and the value of vehicles and parts, exclusive of engines and tires, was \$2,204,388. In February 1779 vehicles were shipped and in January 1841.

MORE CONVICT MADE BRICK.

The paving brick plant of the Junction City Clay Products Company, Junction City, O., has been leased by the Ohio Board of Administration, and it is purposed to operate this with convict labor, the product of the plant being furnished for paving purposes wherever this can be used to good advantage in the state. This work is to be a practical trial of a plan which, if successful, will be increased, and the expectation is that eventually a sufficient supply of brick can be produced to meet the ordinary construction and repair requirements of the highway department of the state.

KELLY-SPRINGFIELD TIRE EARNINGS.

The gross profits of the Kelly-Springfield Tire Company, New York City, for the year ending Dec. 31, 1913, were \$1,264,567, and the operating expenses for the same period were \$716,289, with a balance of \$548,278. The assets of the company of the date stated were \$9,835,060, with the plant, accounts, patents, trade marks, good will, etc., valued at \$7,888,618, and the liabilities included preferred stock to the value of \$1,149,500, common stock to the value of \$4,000,000, debenture bonds to the value of \$2,850,500, and surplus of \$1,449,799.

FUTURE IN THE BALANCE.

The future of the Admiral Motor Car Company, St. Louis, Mich., which has been doubtful because of differing conditions, has not as yet been determined, and is more or less dependent upon developments. The stockholders still believe in the possibilities of the concern, and for that reason decision has been reached to manufacture the 3000-pound machines that have been ordered, and when these have been completed to make another survey of the situation. One possibility is a reorganization.

SAVINGS OF PARCEL POST.

The registration number plates used in New York State will this year be about 140,000 sets of two each, according to the estimate made by the office of the secretary of state at Albany, the greater part of which are distributed to the owners from the state capital, and previously these were sent out by express at an average cost of about 35 cents a set. They are this year distributed by parcel post at an average expense of 12 cents a set, which will result in an estimated saving for the year of approximately \$25,000.

GRUENFELDT GOES ABROAD.

Emil Gruenfeldt, chief engineer for the Baker Motor Vehicle Company, Cleveland, O., has sailed for Europe from New York and expects to remain about two months. Much of the time he will be absent will be passed in Germany, where he will enjoy a vacation, but he purposes to make careful investigation of recent European motor vehicle development before he returns.

STICKNEY IS DISTRICT MANAGER.

P. L. Stickney, who was formerly associated with the Service Motor Car Company, located in New York City, and who is one of the best known truck salesmen in the East, has joined the Palmer-Moore Company in the capacity of district manager and will have his headquarters in the Metropolis. He will have jurisdiction over a considerable territory outside of New York.

WILL MAKE TRUCK MOTOR GOVERNORS.

The Kramer Governor Company has been organized at Milwaukee, Wis., by Benjamin G. Kramer, J. W. Anderson and Max Gessler, with capital of \$125,000, to produce a governor especially designed for the control of truck motors. The company is established in the works of the B. G. Kramer Company, 243 Lake street, and will shortly begin construction of the device.

PRIVATE TAXICAB SERVICE.

Lord & Taylor, a firm operating a department store in New York City that is one of the best known of the leading commercial enterprises of the metropolis, has purchased two White taxicabs, which are to be devoted to the service of its customers. This is believed to be the first instance of a retail store installing cab service exclusively for the benefit of its patrons.

The offices of the Norma Company of America, maker of roller and ball bearings, were on April 11 removed from 2024 Vesey street to 1790 Broadway, New York City.

THE MOTOR TRUCK

Vol. V**MAY, 1914****No. 5**

The Publisher's Page

The realization of the enormous sums needlessly expended that can be annually conserved through change of methods, has directed the attention of the world to the possibilities of transportation economy, and those who have studied the subject understand that while motor vehicles are the means by which haulage can be best done, it will be necessary to systematize methods now the vogue.

By this is meant that the same condition obtains with reference to highway vehicle use that can be found with civilization generally. Betterment can only be wrought by organization and concerted action.

The motor vehicle, no matter how well constructed, is a failure unless so used that its possibilities may be realized. If the conditions of service are such that its speed and capacity cannot be utilized to the fullest degree the owner is the loser. He can control his employees and his organization, but he cannot govern the haulage of other concerns and individuals. There is no co-operation, no understandings that might be reached and no inclination to enter into engagement that might be remarkably productive.

The use of the motor vehicle has awakened the people, and those who sought to economize have learned that while they as individuals have decided limitations, it is well within the range of practicality to gain far greater benefits through systematization. This has been applied to street traffic to some extent, but those who are progressive understand that transportation to be highly efficient ought to be regulated with reference to each work, and that this means that schedules and assignment of definite hours for constant and variable haulage will be productive in largest measure.

Great industries and undertakings of magnitude have been made possible through organization and system. There is no reason why similar methods could not be applied to the use of terminals, piers and places where freight is received and delivered. Business requirements can be adjusted to conditions with comparative ease if clearly understood.

But the people must be educated, and this can only be accomplished through the instrumentality of the motor vehicle industry, which has, or can have, the organizations, the resources and the opportunities for disseminating public information. The result will not be what the people desire, but what the industry makes.

The MOTOR TRUCK is not a medium for circulating publicity that will benefit the individual only, unless this will be of material advantage to its readers. It is devoted to investigations of conditions that will not only be beneficial to the industry and the trade, but to the people of the nation. As a business man's magazine it deals with large problems, it investigates conditions with which haulage can be associated, and it reflects the best of all measures by which to judge—experience. Its promotive influence is very great, because it reaches the thinking men of affairs, who formulate principles and policies and have the ability and the forcefulness to apply them.

The MOTOR TRUCK is an authority on transportation by highway vehicle, and in promoting economies it necessarily treats of a diversity of subjects. The present number is an example of what each succeeding issue will be, and it will be as much better as is possible to produce it. Incidentally, this is a number worthy your very careful study. It contains the first system ever published by which actual work, operating expense, operating revenue, net earnings and actual value of equipment can be kept and accurately known to a day. This in itself is a work of decided importance. Examine it and draw your own conclusions.

NO FENDERS IN MILWAUKEE.

OHIO LAW STILL "BUSTED".

The owners of motor trucks used in the streets of Milwaukee, Wis., will not need fender equipment for a considerable time to come, for the proposed ordinance requiring fenders was rejected by the city council. But this result was obtained largely through the activity of the officials of the Stegeman Motor Truck Company. All owners of machines operated in Milwaukee were notified by the letters sent out by the firm, and investigation of accidents in the city developed that only about 10 per cent. of the motor vehicle accidents were caused by trucks. Not only this, but in every instance injury was caused by falling between the front and rear wheels, which possibility could not be safeguarded by fenders. With these facts and that no practical fender has yet been produced, and maintaining that to require such equipment would be costly, unnecessary and would serve no good purpose, the company and its allies convinced the councilmen that the ordinance as proposed was worthless.

The Franklin County court of appeals of Ohio, to which the decision of Judge Kinhead that the Warnes law, which was to become operative in that state Jan. 1, was unconstitutional, was carried by the state, has affirmed Judge Kinhead's opinion as to unconstitutionality, and declared that the old motor law was in effect. As all decisions have been adverse there is doubt that the state will carry the case to the state supreme court. The court decided that the law was intended to produce revenue and was not for the control of motor vehicle users through the police power of the state. As two-thirds of the revenue raised by the law would go to the general fund the court decided this phase was unconstitutional. The law proposed to charge registration fees ranging from \$5 to \$18, according to the horsepower of the motors.

That part of the law which provides for the registration of manufacturers and for the licensing of all drivers was affirmed.

VOL. V.

PAWTUCKET, R. I., JUNE, 1914

No. 6

MOTORIZED MUNICIPAL EQUIPMENT.

Changes from Animal Apparatus and Vehicles by States, Cities, Towns and Commission Administrations Result in Decided Economies, Largely Increased Efficiency and Materially Improved Service That Benefits the People.

MOTORIZED equipment is recognized as an absolute necessity for the public service of the nation, state or municipality, and is especially applicable to every municipal department, whether large or small, or whether devoted to safety, or protection of public welfare. But in addition to these the divisions that have work that may be regarded as routine in character, in which economy is a factor, can utilize motor vehicles for transportation with equally satisfactory results. One will admit that the necessity for economies is as cogent with municipal administration as with the private enterprise.

One might maintain that the needs of a community are proportionate to population, but when the conditions are analyzed it is apparent that the necessities are practically alike, the real problem being the number of units that will best serve. The service cannot be measured by dollars and cents in municipal departmental work, for the factors for judgment are vastly different than are those by which the business man determines his own requirements.

Economy is the principal basis for adopting motor vehicles or apparatus, but the saving may not appear in the expression of money values, nor in a given period of time. Those who advocate motorization are often at loss to demonstrate practically just what results will obtain. Conditions are not uniform and departmental requirements differ greatly. The view of the taxpayer may be concentrated on a money value,

but the real possibilities cannot be understood unless the future is considered.

Considering a fire department as an example: The problem is the change from animal equipment with the least expense, and generally this is done progressively because of the large initial cost, which is

Delivery Wagon, 1500 Pounds Capacity, in the Service of the Massachusetts State Infirmary at Tewksbury.

in this manner carried through several years. But the greater degree of protection, without increase of stations, apparatus or men, means a great saving in department maintenance expense, and the suburban growth can be taken care of. Without any other change than of apparatus a town or city can increase its fire department efficiency 100 per cent.

The motor equipment can be used for many years,

Group of Wagons Used by the City of Boston: From Left to Right—Emergency Wagon of the Water Department of the Department of Public Works; Public Ground Department Wagon; School Committee's Transfer Wagon, and Truck in the Service of the Park Department.

and the operating economy will pay the interest on bonds that will provide a considerable part of the expense, so that the initial cost may not necessarily be large. But were the operating expense larger there would still be the other factors for economy, which are too potent to be overlooked. The same statements will apply equally well to administration of police departments.

As to Converted Equipment.

Conversions and adaptations of animal equipment are practical, but are not as satisfactory as specially built equipment, and though having greater speed and reserve will not have additional capacity, which is usually a primary reason for making a change. Other municipal and state departments, which have to do with permanent improvements, construction, maintenance and the like, where the work may be constant or seasonable, require facilities that will serve all normal requirements and yet be adaptable for widely differing purposes. Where the service is variable the real need is convertible vehicles, which may be operated to the greatest advantage un-

der a considerable variety of conditions of service.

The extent to which municipalities have motorized their departments is seldom realized, even by those who have had occasion to make inquiry or investigation, and how cities and towns have adapted machines to practically every purpose is a study that

The White Ambulance Equipment of the New Haven, Conn., Hospital.

ought to interest every citizen, because of the undoubted advantages and economies.

In Water Department Service.

The water departments of a number of New England towns and cities have used motor vehicles with decided success, obtaining a greater degree of satisfaction and lessening the expense to an appreciable extent. The Metropolitan water and sewerage board, which maintains the metropolitan park system in Boston and its suburbs, is a state body, being a division of the administration of the commission. This division has used a 1500-pound White wagon since Nov. 1, 1910. This is utilized for emergency work, carrying a force of men, with such tools and supplies as may be required, who repair water and sewer mains.

The metropolitan district covers a large area, and a great

Ambulance Owned by the Town of Webster, Mass., to Convey the Sick and Injured to Hospitals at Worcester, Mass.

Examples of Small City and Town Fire Apparatus: Upper Left Illustration, Squad and Hose Wagon at South Manchester, Conn.; Upper Right Illustration, Six-Cylinder 60 Horsepower Combination Chemical and Hose Wagon at Easthampton, Mass.; Lower Illustration, Combination Hose and Chemical Wagon at Malden, Mass.

deal of the time of the men would necessarily be required for travel were it not for the use of the White machine. In fact, before the use of a motor wagon several repair gangs were located in different sections, and with animal wagons they could not do as satisfactory or as efficient work as is now done with one gang and a single machine.

The Brockton, Mass., water department makes use of a 3000-pound White wagon that has been in service since March 30, 1913. Practically every kind of work is done, construction, repairing, installation of meters, etc., the workmen being carried from one job to another. The pumping station is at Silver Lake, 12 miles distant, and the machine is used for haulage of supplies as well as emergency trips. The wagon is fitted with tool boxes at either side, which also serve as seats for the workers. On the back of the driver's seat is a box that contains a card index showing the location of every meter and water gate and hydrant in the city, so that the foreman has immediately specific information relative to any work that he may be required to do. Up to June 1 it had been driven 6800 miles and the total expenditure for maintenance, aside from tires, gasoline and oil, was \$16.75. The statement is made that with the wagon two men do

the work for which four men and two horse wagons were required. The machine is kept in a garage maintained by the department.

In Attleboro and Boston.

At Attleboro, Mass., a town that is about to become a city, a 3000-pound White wagon is used for practically all of the work of the water department, this being placed in service about two months ago. The town as now constituted has a number of villages from a half-mile to three miles distant from the centre, and all of these are served with water. The water mains cover a large area, and economy demands that they be maintained with the greatest economy. The use made of the machine is to take a gang and tools and supplies about, remaining with the men and economizing their time by quick trips between places where work is done. On the basis of mileage the ma-

The First White Specially Equipped Wagon, Built for the Boston Protective Department.

Types of Special and General Service Wagons: 1, 3000-Pound Machine Used by the Attleboro, Mass., Water Department; 2, Emergency Wagon of the Boston Water Department; 3, 1500-Pound Wagon Used by the Framingham, Mass., Water Department; 4, 3000-Pound Truck Attached to the Massachusetts State Arsenal; 5, Transfer Wagon of the Boston School Committee.

chine does not make a good showing, but judged by the superintendent of the department it is a great economy, for it has lessened the number of men necessary. The department used a ton machine for a considerable time before the White wagon was pur-

chased, it being replaced because it had not sufficient load capacity. This machine is kept at the department's garage and is maintained by its employees.

The Boston Public Works Department, water service division, uses a 1500-pound White wagon for emergency work, this being required to respond with a crew of men to fire alarms, and to all places where they may be required to control the water to prevent losses and damage from accident. Quick action is always necessary, the calls are frequently overlapping, so to speak, and the men are on duty day and night. The runs may be from a block or two to any distance served by the city's water service. The city is about 15 miles in greatest length, and approximately nine miles wide, and this area must be covered by the emergency crew. Obviously this work could not be done with so few men or so satisfactorily with any other form of conveyance. The wagon is equipped for carrying the tools usually needed for all work that the crew is expected to do.

The water department of the town of Framingham, Mass., has a 1500-pound White wagon that has been in service for about 20 months, and during the first 18 months the cost of operating the machine was \$1350 less than had been paid for haulage during the 18 months preceding the acquisition of the motor equipment. But in addition to this the report of Water Commissioner Arthur C. Winch stated that the time of transportation had been so much reduced that much labor that was formerly unproductive could now be regarded as productive. This saving alone was believed to be sufficient to cover the item of depreciation. During the first year the wagon was driven 7375 miles, used 1145 gallons of gasoline and 19 gallons of cylinder oil, and the cost of tires was \$228.92, including repairs, and the expense of repairing the machine was \$32.95.

Special Service in Lynn.

The water department of the City of Lynn, Mass., is extending a supply main to the Ipswich river in the town of Lynnfield, and this is being constructed of 36 and 30-inch iron pipe. About 7000 tons of pipe will be used. This pipe is brought to Breed's wharf by barge and landed by derricks, and it must be hauled and distributed along the line of construction. Each pipe section weighs 2.5 tons, approximately. When the haulage was estimated the possibilities for economy by purchasing and operating a motor truck as against a contract for the work were considered, and the department decided to buy a five-ton White truck, which was equipped with a winch driven by the motor. This winch consists of a cross shaft carrying a large bevel gear, which meshes with a pinion on a shaft mounted above the transmission gearset, this pinion shaft being driven by a chain from the gearset, which is used to drive the winch either forward or backward. The cross shaft carries a cable drum at either end.

On the chassis is a platform with openings directly above the drums of the winch, and on the sides of the

platform are long rolls that prevent the cable binding against the side members. Midway of the platform, at either side, is a heavy hook that is used to secure a large single sheave block, and beneath the hooks are eyes to which the end of a cable is made fast. The platform carries two transverse bolsters. When the machine is loaded two iron-shod skids are placed from the ground to the platform, with the lower ends close to a section of pipe. The cable is secured to the eye on the opposite side of the platform, carried across the chassis and down and around the pipe, and thence back to the block, and then forward to and around the drum of the winch. The engine is started and so compounded is the power that the pipe is rolled up the skids to the platform and into place, one man merely guiding the pipe. The pipe is chocked with blocks secured by pins. Two pipe sections make a full load. On unloading the process is reversed.

Also Hauls a Trailer.

But the truck is required to haul a trailer. This consists of a large and high arched steel axle mounted on two very large wooden wheels. At the centre of this axle is fixed the end of a squared timber that serves as a pole. At the other end is a steel strap that carries a large eye. This serves to couple the trailer to the truck, a simple pin coupling being used. On the rear end of the pole is mounted a heavy cross shaft carrying two ratchet gears, and a lever arm that is extended by a long pole. On the shaft is a drum. The trailer is pushed with a wheel at either side of a section of pipe, a chain passed around the pipe and made fast to the drum above the axle, and by means of the lever the pipe is raised against the axle, this insuring sufficient road clearance. The lever is bound and the end of the pole lifted and coupled to the truck. Two of these trailers were constructed, so that one may be loaded while the other is on the road. This saves time loading.

The haul will average about 4.2 miles. About 6000 tons of the pipe is 36 inches diameter and the other 1000 tons is 30 inches diameter or less. There was approximately 2400 sections of pipe 36 inches diameter, and with three to a load this represented about 800 loads. The truck has been hauling 18 sections a day on an average, or about 45 tons, and at this rate the work will be completed in about 133 working days. The smaller pipe will probably require about 30 days additional. With horses two loads could be carried daily and a team of four would be necessary to haul a similar load. The saving is estimated at 73 cents a ton, or \$5110 for the job, and this is more than the cost of the truck. When the haulage is completed the truck will be retained by the department and other uses, general haulage, made of it. By that time it will have more than saved its cost. The department now has two Federal wagons that are used for general purposes, and two touring cars. These are kept at the combination stable and garage of the department. As the police department has a patrol wagon and an ambulance, there is probability that a municipal garage

Machines in Hard Public Service: 1, 3000-Pound Truck of the Brockton, Mass., Water Department; 2, Emergency Wagon of the Metropolitan Water and Sewerage Board, Boston, Mass.; 3, Emergency Wagon of the Electric Light Department of the Town of Danvers, Mass.; 4, One of the 10 White Police Patrol Wagons Used by the City of Boston.

will be erected that will store the present equipment and have reasonable provision for increase.

The town of Danvers, Mass., operates a municipal lighting plant, and this department has used a 1500-pound White machine for about two years and a half,

Five-Ton White Truck and Special Trailer That Is Now Hauling 7000 Tons of Water Main Pipe at Lynn, Mass., Saving More Than the Cost of the Machine in This One Work.

which has been used for all departmental purposes, construction, maintenance and emergency. It is necessary to utilize a single machine because of the town being comparatively small in population and with scattered settlements. The workers employed are few and while construction and maintenance are done by day, emergency work is necessary at night, so that the machine may be said to be constantly in use. Great saving is made in carrying material and the workmen, while for emergency service the repairs are made with greater rapidity and a much larger area served than would be possible with animals.

The State of Massachusetts has a 1500-pound White wagon in the service of the State Infirmary at Tewksbury. This is a large institution, located some distance from the town, on a hill with the buildings widely scattered. The machine was bought nearly three years

ago for general transfer work between the infirmary and the town, and it has been used practically all that time for conveying passengers to and from the station, making emergency trips to Lowell, and carrying

Five-Ton White Truck That Is Used by the Street Department of New Bedford, Mass., for Construction and General Haulage.

freight. There is a White touring car attached to the infirmary, as well as two small machines that are used for taking food from the general kitchen to the different divisions, a work that is done three times each day.

These machines are now kept in a garage, although for a long time they were stored in sheds and given scant attention.

The state has a 3000-pound White truck attached to the Massachusetts Arsenal at Watertown, which is used for the general haulage of freight and material, for the equipment and munitions for the state military organizations are distributed from the arsenal, and there is a great deal of transfer work between this store and the different points where the commands and state armories are located.

Three-Ton Dump Truck with Special Body Built for the Highway Department of the City of Lawrence, Mass.

The City of Boston has 10 1500-pound White chassis fitted with covered bodies that are used by the police department as patrol wagons, the first of which was placed in service about 2.5 years ago, and these are in constant service, giving satisfaction that is best demonstrated by the increase of numbers. Similar wagons are in service in Worcester, Brockton, Somerville, Milton, the Metropolitan district, and Woonsocket, R. I. These machines are adapted for emergency use as ambulances, having a small stretcher included in the equipment.

The City of Boston makes use of three 3000-pound wagons in the public grounds, school and park departments, these being in service that is more continuous and does not necessitate the hard usage that is inseparable from the fire and police departments. These machines are Whites. The city has a number of trucks attached to the department of public works and the health department, these being utilized for construction, maintenance, street cleaning, garbage removal, street sprinkling and oiling and other purposes.

In Hospital Work.

The saving of time in hospital work cannot be overestimated. In the event of accident or illness every second gained is valuable, and with this as a potent factor hospitals and municipalities are rapidly providing motor equipment. An example of admirable ambulance facilities is that of the New Haven, Conn., hospital, which has two 1500-pound White chassis fitted with splendidly equipped bodies. The service desirable for the town is illustrated by the ambulance owned by the town of Webster, Mass., for as there is no local hospital many persons, ill or injured, are sent to Worcester. The trains are not frequent, and to insure against delays and take patients to the hospital direct, without a transfer, as would be necessitated were they sent by train, the ambulance was bought two years ago. As a charity its purchase has been justified many times. When not in use there is practically no expense, and it is always ready for service.

In Lawrence, Mass., the street department of the city has a three-ton White truck with dumping body in constant use, and thus far the results obtaining from its service have been especially satisfactory. The street department of New Bedford, Mass., is using a five-ton White truck with a power dump body. This has been worked for about a year, hauling crushed stone where street work is progressing, and doing general work at other seasons. These are excellent examples of municipal equipment that will serve for general utility work.

In fire department service there are no machines that are given harder work than those of the Boston Protective Department. This is really a salvage or property saving division, that, while generally assumed to be attached to the Boston fire department, is maintained by the different insurance companies. There are four companies, located in different sections of the city, and one or more of them answers every

alarm of fire. This means that they must go to all parts of the city and speed is the real factor, for time is valuable beyond estimate. The runs are made as quickly as possible, and this means hard usage for the machines. But they are well maintained. Four special White wagons are used by the department, the success with the first resulting in additional orders. The city of Malden has a White combination hose and chemical wagon that has been in service for about two years. Excellent examples of equipment adapted for towns are to be found at Easthampton, Mass., and South Manchester, Conn., both of which have combination hose and chemical wagons mounted on White chassis.

HEAVY TRUCK MILEAGE.

The heavy truck that is driven an average of 35 miles a day is believed to be doing as large a mileage as can reasonably be expected, considering the time necessary for loading and unloading, but an experience with a Garford truck used by a contracting firm for a month, with 26 working days, is of especial interest in that it was driven during that time a total of 1592 miles. This was an average of 61.2 miles, or approximately 26 miles a day more than the average expectation. If the machine were driven continuously for 10 hours this would show an average speed of 6.12 miles an hour, and if the driving time were seven hours, this showed an average speed of 8.75 miles an hour, which is very close to the maximum that would be expected of a machine of this type.

The sales force of the General Motors Truck Company has been joined by J. L. Bergs, who was sales manager and superintendent of the Johnson Service Company's factory at Milwaukee, Wis., and was later associated with the Fritchle Auto & Battery Company, Denver, Col.

Assistant general manager is the title of W. O. Rutherford, who for four years has been assistant to H. E. Raymond, second vice president and general sales manager for the B. F. Goodrich Company, his appointment having just been announced.

J. H. Keidler, who was connected with the General Motors Truck Company and the Northway Motor Company, both of Detroit, Mich., has been appointed general superintendent for the Standard Motor Truck Company's plant in Detroit.

W. G. Tennant has resigned from the vice presidency of the Stewart-Warner Speedometer Company, Chicago, Ill., and will again associate himself with the Tennant Motor Company, of which he was founder.

The Universal Motor Truck Company, Detroit, Mich., has appointed Walter L. Jordan its western sales representative.

MOTOR GENERAL STORE.

Enterprising Greenville, Mich., Merchant Carries His Goods to Customers.

A mobile general store, that is moved about 50 miles each day, and which serves about 500 families each week, may appear to be a visionary proposition to those who are accustomed to do their buying at different places, and who indulge in "shopping" more from the satisfaction of curiosity than from actual economy, when the value of the time is considered. But as a practical enterprise, conducted by E. A. Eriksen, a Greenville, Mich., resident, the motor store has not only been profitable, but the service and convenience have attracted a very substantial and constant patronage.

Mr. Eriksen believed that if he were to sell goods at prices that would compare with the general market, and could make the deliveries in person to the people, he would at least have the advantage of dealing with them personally, and he could meet any requirements that might ordinarily be made upon him. Having a practical store experience he decided that a well diversified stock, such as might be found in a general store, that could be replenished daily and kept to a standard, would be attractive to customers.

He bought a Republic 3000-pound delivery wagon chassis and on this installed a body that is completely enclosed, having doors at either side to convenience handling, and with shelves, racks and bins for the storage of goods, all so arranged that while easily accessible a large diversity could be carried. The body is stoutly constructed, so as to afford the fullest protection, and all the doors may be locked when this is necessary. The roof of the body is surrounded by a pipe rail so that boxes or cases may be carried on it without possibility of loss.

The arrangement of the chassis is conventional

enough, but the body is decidedly unusual in its appearance, although not unsightly. Each morning the stock is brought up to standard, all kinds of groceries, provisions, fabrics and various articles of household use being stocked, and it covers a regular route, going into the country sections where time and in some circumstances conveyances are necessary to reach the stores. The machine stops for the different customers, who select and are immediately delivered their purchases, an average of more than 70 calls being made a day. Not only this, the motor store will buy certain fruits and vegetables, paying cash, which means that the farmer is able to obtain good prices without the necessity of marketing, a material factor at the season when time is particularly valuable.

Special orders are taken and filled when the next trip is made, and in this way the farmers are given a service they particularly appreciate. The demands for the visits of the store are surprisingly numerous, and the success of the business is limited only by the number that can be served. Financially the store has been much more productive than Mr. Eriksen believed, and while it has been quickly developed it has been demonstrated to be a very substantial and certainly a productive enterprise.

KNOX SELLING ORGANIZATION.

The Knox Motors Company, which succeeded the Knox Automobile Company, announces the appointment of George M. Davis as assistant sales manager. Mr. Davis was associated with the E. R. Thomas Motor Car Company of Buffalo, N. Y., and later was with the Pierce-Arrow Motor Car Company for four years, and recently he has been connected with the Packard Motor Car Company at Albany. Charles F. Barrett has been made advertising manager. The organization practically combines the sales and advertising departments.

Following the confirmation by Judge Morton of the United States district court for Massachusetts of the transfer of the property of the Knox Automobile Company to E. O. Sutton, the plans for production and selling were determined. The company had branches in New York, Boston, Chicago and Kansas City, and with the establishment of the company on a certain basis, the distributing organization will be developed broadly. Numerous applications for agencies have been received. Production orders have been given for a number of Knox-Martin tractors, fire apparatus, and latest model pleasure cars.

Republic Chassis Fitted with a Special Body and Stocked and Used for a General Store by E. A. Eriksen, Greenville, Mich.

ADAMS BROS. COMPANY EMBARRASSED.

The Adams Bros. Company, Findlay, O., maker of the well known Adams trucks, was, May 15, placed in the hands of a receiver, W. D. McCaughey being named by the court to administer the affairs of the concern. Because of business depression the company was embarrassed and a condition was reached where rearrangement of its finances was imperative. This was undertaken and there was reason to believe that the proposition would be successful, but just before the determination disagreements arose among those at interest as to the division of affairs, and this resulted in the petition for a receiver. No statement has yet been made relative to the assets and liabilities, and the future of the company is as yet uncertain.

LARGER "PHILADELPHIA" QUARTERS.

The Philadelphia Storage Battery Company's service station in New York City has been removed from 562-6 West 52nd street to 651-5 West 43rd street, this being necessary to meet the demands of the rapidly increasing business of the concern. The station occupies the entire ground floor of the building, this affording much larger area, and it is equipped with modern facilities for construction, repair and the charging of storage batteries, while there is a salesroom that is of sufficient proportions to display a stock of batteries of all types and sizes, as well as supplies of all kinds. The station is in charge of Walter L. Thompson, the New York City sales agent, who has offices at 1789 Broadway, that city.

MOTOR TRUCK FOREIGN TRADE.

The opportunities for export trade for American built machines, both for pleasure and for freight service abroad, have received the attention of numerous sales managers, and G. C. Frey of the Kissel Motor Car Company states that his concern has received many inquiries. He says in connection with this that he considers it as an indication that the American automobiles are not only being regarded with increased favor, but that the future will probably be bright for exporters generally. American business men are studying the methods of other nations carefully and the result will be a better mutual understanding. The interest evidenced in freight wagons and trucks is so large as to be decidedly surprising, which presages trade relations of a highly satisfactory character with many foreign markets.

MOTOR TRUCK STORE.**St. Louis Delicatessen Dealer Carries His Stock to His Customers.**

The Autocaressen is the name that William Goldstein of St. Louis, Mo., has bestowed upon the vehicle in which he conducts a novel business, or it may be that he has chosen this with a view of designating the business, but in any event St. Louis is the only city in America that can boast of a complete store housed in a motor truck. In the general acceptance of the public, delicatessen is understood to mean a store where food can be procured ready for the table, and such establishments, which originated in Europe, have become very popular within a comparatively few years. Where there is a considerable number of people of German origin such stores are numerous and many of them have very varied stocks, some specializing in imported table delicacies.

A delicatessen store is common enough, but when a man conducts one that moves through the streets when and where he will, serving all who may favor the general plan of having the store and its stock brought to their door, with as great a variety as might be found in a permanently located business, the proposition becomes novel from numerous aspects. One might assume that the volume of transactions would of necessity be large to meet the expense of operating, and regard the idea with material doubt, but Mr. Goldstein's experience has been that the people have taken kindly to the Autocaressen, and their patronage has been liberal and satisfactory.

The store is primarily a 3.5-ton B. A. Gramm's truck chassis, this being a standard construction, and on this is installed a body specially designed by the McCabe-Powers Carriage Company of St. Louis. The construction has a resemblance to the ordinary railroad dining car when viewed from the side, there be-

The Autocaressen, a Motor Truck Delicatessen Store Operated in St. Louis, Mo., with Much Success by William Goldstein.

ing a series of plain and ornamental sash windows rather high above the floor, with a sliding door with a glass panel about a third of the length from the forward end. This body extends from the radiator well back over the end of the chassis frame. The body is somewhat wider than the chassis frame, and at the forward end it fits over the fenders and the short running board. The front of the body is full width, with a series of windows, the lowest of which is just above the top of the radiator.

The roof of the body is a monitor type with a low hip in which are five windows on either side, and along the side edges of the roof are low rails. Because of the width of the body the front fenders and the running boards are well under the sides, but both are retained to secure the protection of the body from road mud and water thrown by the front wheels. There is a folding step at the side, by which the machine is entered, and handrails are at either side of the door. Centred over the rear axle is a low side window at either side, this being intended for display purposes, and a considerable assortment can be arranged within view of the customers who do not care to enter the body. The interior height of the body affords full head room for a very tall person. The windows are in part glazed with colored glass and with the highly ornamental finish the machine is very attractive.

The forward end of the body contains the driver's seat and the control levers and pedals, while the portion back of the seat is arranged for the storage of all kinds of stock and so that it may be carried without damage or loss, and in such condition that customers may inspect it before purchasing. The machine is sent over stated routes each day, the driver signalling the customers, who make their selections and receive their purchases immediately.

The practicality of the Autocaressen has been fully demonstrated by Mr. Goldstein, and it has proven to be a very profitable investment, although it would not be productive in all business enterprises.

The wholesale price of gasoline as supplied to garages is now 15 cents a gallon, this being established in different sections of the East about June 1, both by the Texas and Standard Oil companies. The Standard Oil Company's Pacific Coast price was at approximately the same time reduced from 16 to 15.5 cents a gallon. The high price, 17 cents a gallon, was fixed in January, 1913, and the first reduction was to 16 cents in November, 1913.

The Holtzer-Cabot Electric Company has begun the construction of a new six-story factory building in Armory street, in the Roxbury district of Boston, which will be completed and equipped early in 1915. The structure and the facilities will be of a character to insure the highest grade production and the greatest efficiency of the workers.

GMC ELECTRIC TRUCKS.

The General Motors Truck Company, Pontiac, Mich., has just published a new catalogue of the electric wagons and trucks built by its electric division, and this describes the distinctive features of design and construction of the GMC machines. These include the three lengths of chassis for each type of wagon or truck, which have capacities of 1000, 2000, 3000, 4000, 6000, 8000, 10,000 and 12,000 pounds, in which the batteries are carried on the chassis and in a compartment under the seat of the driver. Another feature is the flexible shaft drive from the motor to the countershaft, while in addition to this are the location of the controller, the safety switch and the ampere-hour meter under a hood in front, and the placing of the control lever in combination with the steering wheel, as well as the operation of both service and emergency brakes by pedals.

Following detail specifications, which are standard throughout, chassis dimensions for each of the three sizes are given, the prices of the chassis with Edison, Exide or Philadelphia batteries, and the approximate price of the different types of bodies that may be installed upon them.

The chassis dimensions, besides giving the proportions of the bodies that may be installed, include the wheelbase, tread, overall length, width of frame, overall width of chassis, height above ground when loaded, road clearance, allowable body weight and tire sizes, as well as the equipment that is furnished. The battery detail includes the makes, types, speed an hour, miles on a charge, length and width of battery boxes, and the prices of the chassis and battery, while the body data relate principally to the approximate prices of different types when installed on the different chassis, but do not include more than what may be regarded as standards. In addition the catalogue shows a number of different types of bodies that are in service, so that those desiring can identify the models and types that are illustrated.

The Allen Motor Company, Fostoria, O., has purchased the plant of the Atlas Manufacturing Company in that town, and the latter concern will locate its plant elsewhere. The Allen Motor Company has plans to build 5000 cars in 1915 and required greatly increased facilities. The Atlas plant was devoted to the production of crankshafts and parts, and this line will undoubtedly be continued.

The San Francisco branch of the Moreland Motor Truck Company, Los Angeles, Cal., is now in charge of George V. Lyons, formerly manager of the Alco Motor Sales Company of Los Angeles.

W. C. Hood, sales manager of the Standard Motor Truck Company, Detroit, Mich., has appointed as his secretary, J. E. Morgan, who was at one time connected with the Metzger Motor Car Company.

EXPLOITING MOTOR TRUCK FIELD IN CUBA.

THE exploitation of motor vehicles in foreign countries may be regarded by the executives of the selling organizations as being simply demonstrations of the qualities of machines, and this work may be believed as practical as it is in different sections of the United States, but there is a vast difference in the conditions to be met with, and those who have to do the actual pioneering or missionary exploiting find they are confronted with situations that require the greatest resourcefulness and knowledge to deal with them.

In European countries, where there are excellent highways, much better than the average of American roads, the great need is to convert the prospects to the qualities of the machines, because the manufacturers of Europe as a rule have material and workmanship that are excellent, and all motor vehicles are carefully finished. The American plan is to regard utility first of all and to place a secondary value on finish so far as it does not affect the actual operation or endurance of the wagon or truck.

But where the operating value of the machine has been proven and its qualities established, then comes the possibility of selling at lower prices through manufacturing superiority and quantity production. In countries where the roads have never been designed for economy in transportation, where time or labor are not regarded as having definite value, and where animals have been used for centuries, highway conditions are a very potent factor.

West Indian Road Conditions.

This statement can be applied very generally to the West Indian and South American countries. The railroad lines are comparatively few, and the means of transportation are limited to highways that are not

to be compared with roads in the United States. There are fairly good streets and some excellent roads within the large cities, but outside of these the highways are practically paths and trails on which the traffic is by saddle horse or occasional light vehicle, with heavy animal carts that carry comparatively small loads.

As may be assumed the motor wagon or truck can be utilized to good advantage wherever the roads are such that they can be driven to anything like the speed and capacity for which they are designed, but in many instances the men who undertake their exploitation must, in addition to the usual endeavor to disseminate knowledge of mechanical construction and transportation economy, begin a general education of the people with reference to highway development. To conceive what these men must deal with one must understand that the commerce is very largely carried on at the coast and on the banks of rivers that are accessible for vessels, and the interiors are not so easily reached, save by waterways and craft that would mean enormous expense for transporting were time and labor of anything like the value that they are in other countries.

The Situation in Cuba.

Cuba, since the independence of the island, has followed the initiation of the Americans, who developed many of the highways for military purposes, and there is now an excellent foundation for what will eventually be a complete highway system, and this will be of great economic value, for the railroads of the island have small mileage as compared with the United States.

For several months the Federal Motor Truck Company, Detroit, Mich., has had two men in Cuba, who have devoted themselves to practical demonstrations

Federalizing Transportation in Cuba: A, Federal Truck at the Establishment of E. E. Tolkadorff, the Havana Representative; B, Federal Truck at Loading Platform of the International Brewing Company, Havana, to Receive a Load; C, Machine on the Road from Havana to Pinar del Rio; D, Truck Ready to Leave the Plant of the International Brewing Company at Havana, with Special Signs on the Body; E, Loading the Truck in an Havana Street; F, the Truck as It Is Equipped for the Tour of Cuba.

of the work that can be accomplished with a 3000-pound Federal truck, and before their task is completed they will have well exhausted the possibilities so far as the preliminary exploitation of motor vehicles in the commercial centres is concerned. They have not only to interest and educate practical men who may engage in the distribution of motor trucks, but they have to lay the foundation for business that these men can later develop.

The Cuban exploration for business, for this term appears to be rightly applied, is by C. T. Chenevert, formerly assistant sales manager of the Federal Motor Truck Company, and Beckwith T. Havens, who is well known as an aviator with Curtiss aeroplanes, whose feat of flying from Chicago to Detroit, by way of Mackinac, during the summer of 1913 will no doubt be recalled by many.

Mr. Chenevert was Mr. Beckwith's business manager when the latter was giving public exhibitions of aeroplaning, and the two are close friends, as well as business associates. On making a tour of the island several months before they carefully noted the conditions, both in the cities and on the plantations, and found there were many opportunities for the use of motor wagons in the haulage of tobacco, sugar cane and sugar products, fruit and vegetables. These facts were stated to the Federal Motor Truck Company officials and this concern was impelled to immediately make an endeavor to develop business in the island.

Preparation of the Truck.

With this purpose in view a truck was prepared to meet the requirements of the men, who were commissioned to make a tour of the island to establish agencies and sub-agents and to practically demonstrate the advantages of the Federal truck in general haulage work. The truck was equipped with an express body, with a frame that might support a water proof cover, either to protect the loads or the occupants, and this was provided with the usual form of folding canopy over the driver's seat. It also had a tight fitting water proof top to cover the body frame, and means were provided for storing food, cooking utensils, clothing, bedding, etc., for the machine was intended to serve for shelter whenever circumstances necessitated, for there was reason to believe they would frequently be compelled to pass nights away from hotels and where they would be dependent entirely upon their own resources.

The purpose being to exploit the machine, on the cover was painted "El Camion Federal para Transporte Economico", which may be freely translated to mean "the Federal truck for economical transportation", and this is generally displayed, although special signs cover the sides when the machine is engaged in demonstrating work. Of course the sign serves the purpose intended, and does attract people wherever it is seen.

The first attention was given to Havana, where an agency was established with E. E. Tolsdorff, a dealer

in automobiles and accessories, and a number of demonstrations were made to pave the way for the activities of the agent. Then the crew began work in the western end of the island, crossing the mountain ridge and going as far west as Pinar del Rio, making sub-agencies in a number of the principal towns and cities and demonstrating the machine at the plantations of interested men. In Havana considerable demonstrating was done for the International Brewing Company, which has a very well equipped plant and which makes delivery at considerable distances from the city.

Relative to the drive to Pinar del Rio, a letter from Mr. Chenevert, written from Havana, briefly stated the following: "We got back here last night from Pinar del Rio after a very successful trip. Our demonstration load consisted of 10 barrels of bottled beer and five cases, each containing 16 dozen bottles. The total load weighed 4800 pounds. Please don't think that in overloading so heavily we were completely crazy, because we dropped half of this load at Guanajay, about 30 miles out, and the going most of the way was over good macadamized roads. The total run to Pinar del Rio was 118 miles. Our actual running time was 8.5 hours. We used 12 gallons of gasoline and 1.5 pints of oil. We took two days to come back, stopping at the towns en route to show the truck. There is an excellent opportunity to place some trucks with fruit growers, tobacco plantations and fisheries in this section".

The intention of the demonstrators was to start east from Havana and to go as far as Santiago, which is well toward the eastern end of the island, stopping on the way to give demonstrations in the largest towns and at the different plantations. When the introductory work has been accomplished and different prospects have been determined for the benefit of the dealers who will have agencies for the truck, the intention is to go to Porto Rico, where an agency will be established and such sub-agents secured as is believed advisable. The expectation is that the opportunities there will at least equal those found in Cuba.

In addition to the preliminary work in Cuba and Porto Rico, the Federal explorers are studying conditions as carefully as possible to obtain information relative to the possibilities for motor vehicle transportation for the use of the Federal company and its representatives in their future work. The purpose is to make a full report of the investigations when the work is completed.

The New York City service station of the Sears-Cross Company, manufacturer of speed indicators, has been removed to 218 West 65th street. The company's factory is at 147 41st street, Bush Terminal, Brooklyn, N. Y.

The Worcester Speedometer Service Station has been opened at 22 Commercial street, Worcester, Mass., in charge of A. E. Brown, this being a branch of the Stewart-Warner Speedometer Corporation.

GENERAL VEHICLE COMPANY'S PLANT.

Development Made with Plan That Comprehends a Mammoth Industrial Works, Designed to Be Ideally Productive and Standardized from Every Practical Aspect.

THOSE who regard the electric wagon or truck doubtfully when its practicality and utility are considered, who are inclined to regard the industry as uncertain and not well established, undoubtedly are not informed of the progress that has been made by some of the concerns that have been recognized as standard manufacturers of these machines. There are firms that have, since the productions were of sufficient numbers to be regarded as commercial possibilities, been engaged in manufacturing electric vehicles, and generally these have produced both pleasure cars and freight wagons.

The General Vehicle Company, successor to the Vehicle Equipment Company, which built its first wagon in 1900, and since that time has produced nothing but freight machines, has been developed to be a

very large factor in the industry, and what is probably the best evidence that can be demonstrated of the future of the electric car or wagon is the plans that have been determined and the progress made in development by concerns of this character.

Location of Plant.

The company has for a number of years been located at Long Island City, a suburban section of New York City, conveniently reached from Manhattan Island, and there it extended its organization as experience justified. The business the company has done in previous years warranted the projection of a vast plant that will eventually have a capacity of thousands of machines annually. The company has not confined its activities to electric wagons and trucks exclusively, but has made preparations to build a heavy gasoline truck that will be marketed for that class of work for which electrics will not be economical.

These machines have not as yet been placed in the market, and will not be produced commercially until well into the autumn or even the latter part of the year.

The fact that the mechanical vehicle has justified so carefully a developed enterprise is not surprising, but this concern has so planned that expansion will be provided for without in any way interrupting or retarding its productiveness, and systems and methods have been inaugurated that will be continued because of their practicality and economy, no matter to what

proportions the plant may eventually expand.

The provision made for the future is not based on supposition or theory, but on the experience of more than a decade and a certain knowledge of the requirements of the people for means for highway transportation. The building that was until last

The Six-Story Concrete and Steel Building Erected Expressly for the Construction of Electric Vehicles and Bodies.

December the factory, was built about 10 years ago, and when it had been filled with machines and workers and stock until the 90,000 square feet of floor area was so cramped that expansion was necessary in the interests of economy, the company decided on the construction of a very large building, two smaller structures, and such changes as were desirable in the old factory as would meet with immediate needs. In reaching decision, however, an ultimate plan for the layout of the works was determined, and the developments are details of that plan. The construction approved was that which would afford the best endurance and protection consistent with the investment.

The property consists of about 7.5 acres of land divided by a street, one portion being about 500 feet square and the other V shape and consisting of about 1.75 acres. The larger or the west yard at present contains the original building, which is one story in

Building No. 5, Which Has Been Built for the G. V. Mercedes Truck Department of the Company and Which Will Be Enlarged Later.

the centre under the monitor roof, and has a gallery at either side. Connected with this building is a structure about 50 feet square that was used for a battery forming department.

The ultimate plan for the factory comprehends four buildings in the larger or west yard, these to be about 75 feet wide and 500 feet length, from six to 10 stories, and a V shaped building in the east yard to extend along either side of the property, with a building about 100 feet square between the arms of the V, this to be a power plant.

Description of Buildings.

Considering the street between the two yards as a base for description, the buildings will be at right angles from this. The original structure (No. 2) and the new structure erected last year (No. 3) now occupy the centre section of the west yard, and eventually other buildings will be erected north and south of them, these being of the proportions stated, varying in number of stories. The most northerly structure will be No. 1 and the most southerly No. 4, this making up the layout for this yard, the buildings being now numbered to conform to this plan. Eventually No. 2 will be demolished and replaced by another of the same size as the others. These four buildings, of six stories, would have a floor area of about 900,000 square feet, or more than 20 acres; if of eight stories a floor area of 1,200,000 square feet, and if of

10 stories 1,500,000 square feet.

The arms of the V shaped building in the east yard will eventually be known as Nos. 5 and 6 respectively. The power house will be building No. 7.

The present building No. 3 was constructed practically simultaneously with buildings No. 5 and No. 7, but of these neither No. 3 nor No. 5 is completed to full length.

From the accompanying illustrations one will note the relative locations of No. 2 and No. 3 buildings, which are separated sufficiently so as to insure good lighting, the general plan providing for uniform distances between the

four structures in the west yard. No. 3, which is the latest construction, while not yet built to its ultimate proportions, is sufficient to enormously increase the capacity of the plant. The structure has been occupied since last December, although some portions of it were in use prior to that time.

In the East Yard.

Considering the east yard, building No. 5 is partly completed, and this is given over to assembling the G. V. Mercedes gasoline truck chassis, but this is intended, when finished, to be devoted to a gasoline engine testing department and the gasoline truck testing department. The other arm of the V will be part one-story and part two-story, the one-story section to be used for battery forming and the two-story section for battery assembling. In these the gasoline trucks will have engines installed and the electric trucks will have batteries installed. The power house is to be 100 feet square when finished, the boiler house occupying one half and the power house the other. But two bays have as yet been built.

The buildings are erected on made land and to provide a sewerage system the company was compelled to construct a sewer a half mile in length to the Newtown creek. In planning the structures the greatest care was directed to insuring complete protection against fire and to arrange the production so that there would

The First Factory Building of the General Vehicle Company, 100 by 510 Feet, Which Is Known as No. 2 in the General Plant Development Plan.

be minimum handling as the work advanced through the different shops. The No. 2 building was constructed of steel and concrete on concrete piling, the type being what is known as reinforced concrete, with carefully distributed load because of the character of the land. The first floor is designed to sustain a load of 500 pounds to the square foot, the second and third floors 200 pounds and the upper floors 150 pounds. The walls are brick curtain walls, supported at each floor level.

The building is thus utilized: The first floor for receiving, general stores and blacksmiths; the second for a machine shop, the third for assembling, the fourth for wood working and body building, the fifth for painting and trimming, and the sixth for offices and an exhibition room. The building is built to be thoroughly fireproof but in addition every square foot of floor area is covered with sprinklers, and besides this a city water main is connected with a large underground reservoir from which an electric fire pump can deliver 1000 gallons a minute. Fire mains are gridironed about the yard. There is a 50,000-gallon steel tank 30 feet above the roof, which is connected with the yard fire mains and maintains a constant pressure. The building is fitted with standpipes and these are equipped with hose at every floor.

Extreme care was taken in the development of the heating and lighting systems of the building to afford accessibility and economy of operation, the heating being by a vacuum return system, with high pres-

One-Half of the Blacksmith Shop of the Electric Department, Which Is Located on the Ground Floor of the Electric Department Building.

sure boilers so as to provide for possible future generation of electric current with by-product power. The power delivered by the power company is at 6600 volts, three-phase, 60 cycles on the two main feeders, and at 2200 volts, two-phase, 60 cycles on a single auxiliary feeder, the latter to provide a duplicate source of power for the fire pump. The fire pump will take power from either source.

Provision for Power.

The company owns its own transformers, which consist of three banks, the one consisting of three 333 KVA transformers that reduce the voltage to 244 volts, three-phase, 60 cycles, and this current is distributed at this voltage through the works to all the motors. The second bank consists of three 111 KVA transformers that reduce the voltage to 122/244 volts, three single-phase, 60 cycles, and distributes the current throughout the works for all lamps, and the third bank of three 75 KVA transformers is installed at the fire pump and connects on the primary side to the 2200-volt, three-phase feeder of the power company and transforms the current to 244-volt, three-phase, this giving the same secondary as the other transformer.

All of the lighting and power wiring is carried through conduits with special arrangements for protecting it and distributing the current in a most economical manner. The lighting is such that no desk lamps are needed or allowed and no special illumination is required at the tools save in rare cases. Each machine tool is driven by its own individual motor, alternating current be-

A Portion of the Assembling Room in the Electric Division, Which Extends the Full Length of the Fourth Floor of the Building.

A Part of the Mammoth Machine Shop to Which the Entire Second Floor of the Structure Is Given Over, and Which Has Admirable Equipment.

ing used save where variable speed is necessary, when direct current motors are employed, these being driven by current supplied from a motor generator set. The feeders for light and power are run through porcelain tubes which run through the floor beams, so that they are never in danger of damage and there is free overhead clearance for the cranes and other equipment. There are 176 small motors having a total horsepower of 600, and about the same horsepower is utilized for larger motors that drive cranes, elevators, fans, pumps, compressors and motor generator sets.

There are four elevators in the building, one for passenger service to the offices and the other floors; a service elevator of three tons capacity that may be used for passengers or freight; a 5000-pound chassis elevator and a truck elevator with capacity of 7500 pounds.

In No. 2 building is a 15-ton electric crane controlled by an operator in a cage, and in the main aisle of the ground floor of building No. 3 is a five-ton crane that is used chiefly in the stockroom. Three-ton cranes are on either side of the aisles of the third floor for use in the assembling.

The policy of the company is to manufacture its own parts so far as possible, and complete equipment is installed for making the frames and machining all parts. There is no overhead shafting and each machine is driven by a 7.5 horsepower motor. In the blacksmith shop where the work will permit oil fuel is used.

The sixth floor of the building, which is given over to the general offices, is laid out with

a vault 300 feet long in the centre. Besides this there is a suite of private offices for President Wagoner, his assistant and his secretary, a large board room, a private office for Vice President Wesley and his staff, a very large office for the sales department, and separate offices for the service, advertising, accounting, electric engineering, electric division superintendent, a spacious drafting room, private offices for the treasurer and secretary, a restaurant where the 150 persons composing the office force can obtain meals, with a large re-

serve room at the extreme end for expansion. The steel vault is divided into three sections, there being at one end the telegraph office, the telephone operators, and a general file room; further along the vault is devoted to the storage of correspondence, contracts, blue prints and general documents, and one section is to be used for expansion. All of the partitions are of glass and steel.

The keynote of the entire plant is system, there being standardization throughout, even with reference to keys, to colors of piping, and there is a standard design of work bench with a cast iron leg, while everything else is made of steel, this applying to bench drawers, foremen's desks, machinists' cabinets and all of the drawing cabinets, and all of the vault equipment is standardized. Complete record obtains of every detail, this including handling of tools, stock, etc., and inventories and examinations at periodic intervals establish conditions with absolute certainty.

The plant as it now exists is but a small part of

Section of the Factory Stockroom, Which Has in Its Equipment a Five-Ton Electric Crane with Which to Handle Heavy Materials.

what it will eventually be, but the administration has been arranged so that whatever is developed the systems will remain unchanged, and the expansion will be along lines that are positively known.

CITY WILL CONTROL 'BUS LINES.

That it is the intention of the City of New York to maintain control of the operation of motor omnibus lines that may in future be established in that municipality, was forecasted in a paper read by John A. McCollum, assistant engineer of the bureau of franchises of New York at the National Conference for City Planning held recently at Toronto, Can. Mr. McCollum specified the possibilities of motor omnibus lines in the Metropolis, and after dwelling on the importance of these from the viewpoint of city planning, stated that three new companies were desirous of obtaining franchises, while the Fifth avenue line purposed to extend its operations. One condition requiring careful attention was the duplication of some of the routes.

The statement was made that a franchise form is now being prepared which will reserve to the city the control of the operations of the lines, and this will be of a character that will fully conserve the interests of the public. Mr. McCollum stated conditions in some of the sections of the city which are not now well served with reference to transportation and told of some of the material benefits that would obtain with the development of systematic motor vehicle facilities. From the viewpoint of the engineer there are large possibilities and many neglected opportunities yet existing in New York for motor omnibus lines.

The Imperial Valley Transportation Company has been organized at San Diego, Cal., to operate a general freight haulage service between that city and Imperial, which will be inaugurated with six 2.5-ton machines.

The Chicago, Ill., office of the Sheldon Axle Company was removed to the People's Gas building, at Michigan boulevard and Adams street, from 68 East 12th street, May 1.

With capital of \$125,000 the Reedsburg Motor Truck Company has been organized at Reedsburg, Wis., to build several sizes of motor vehicles.

WILCOX SIGNAL SALES MANAGER.

Howard Wilcox, who is widely and favorably known in the motor vehicle industry, has acquired an interest in the Signal Motor Truck Company, Detroit, Mich., and will serve as consulting engineer of the company and will direct the marketing of its products. Mr. Wilcox has had 13 years' experience in designing, building and selling motor trucks, and he has been identified with the building and distribution of Reliance, GMC, Kelly, Standard and Federal trucks, and his work has been of a very broad character.

Mr. Wilcox is credited with developing many of the features of the Kelly machines, and he also designed the Standard motor truck and organized the company that produces it. He was associated with the Federal Motor Truck Company as consulting engineer and was regarded as being thoroughly versed

Cincinnati Gear Cutting Machine, That Cuts 32 Sprockets Simultaneously, in the Fore-ground, and Back of It a Multiple Spindle Drill That Drills 14 Holes at Once.

in the creating and direction of successful sales organizations.

Mr. Wilcox believes that there is a very large market for a standard designed machine, such as the Signal truck, in that it has all the features of the larger trucks and is within the purchasing power of those who must consider price as well as economy and utility.

A great deal of activity in the motor truck market and resulting large sales, and many new agencies, were reported by Robert C. Reuschaw, sales manager of the Reo Motor Truck Company, during a recent tour of the Pacific Coast states.

D. M. Pettit has been appointed advertising manager for the J. I. Case T. M. Company of Racine, Wis.

ECONOMY OF KEROSENE FUEL FOR MOTOR TRUCKS.

THE fundamental principle of business is that, where competition is possible, prices are governed by supply and demand. This is, naturally enough, applied by all owners of internal combustion engines in which gasoline is used for fuel. The prevailing market price is accepted as the determining factor and little or no thought is given to the conditions of production. This is all well enough when pleasure cars are concerned, but with vehicles used for freight transportation, where constant operation and a considerable mileage are required, the price of fuel is well worth consideration.

Gasoline has the quality of vaporizing well, save in extremely low temperatures, while kerosene will not vaporize at less than 90 degrees Fahrenheit, and not readily at that point unless agitated. With gasoline engines starting is usually a matter of turning the crankshaft until a charge of gas is compressed in a cylinder, because the fuel will be sufficiently carburetted to create an explosive mixture, but when kerosene is used vaporization is impossible save when the temperature stated exists. With a warm motor, however, kerosene will give equal efficiency for ordinary requirements, and it has the additional values of being cheaper and practically non-explosive.

Aside from gasoline kerosene is the most logical and practical fuel. The supply is very much larger and with the constantly increasing use of electric lighting there does not appear to be reason to expect that the lamp consumption of kerosene will materially increase, though there are large possibilities for its use for oil stoves and heaters. A considerable quantity of American kerosene is now exported, and if the home market could consume this excess there is little doubt that it would be supplied in preference to meeting the demand of export trade.

According to satisfactory authorities the crude oils will vary greatly in the content of gasoline, but by combining gasoline and the naphthas approximately 16 per cent. of the best crudes will be useful for motor fuel. These same oils will yield about 50 per cent. kerosene, and the content will range from 40 per cent. to 50, so that a reasonable average is 45, or practically three times as much kerosene as gasoline and naphthas, the latter combination being what is now sold in the market as gasoline. The statement means that to produce one gallon of motor fuel three gallons of kerosene must be produced, and as the demand for gasoline is constantly increasing, and in greater ratio than for kerosene, the refiner faces the prospect of eventually making gasoline a very important product and obtaining for it a higher price, securing what is possible for the kerosene.

If the demand for gasoline warrants increase of price there is no doubt it will be exacted. Motor fuels cost much more abroad than in America, which has

led the motor vehicle manufacturers to utilize smaller engines, but to adapt them so that the power can be better applied. Many of the machines used in foreign countries would appear to be extremely underpowered when measured by the horsepower ratings of some American vehicles, but by the use of more gear ratios, and lower power reductions, extremely satisfactory service is obtained. The smaller motors mean greater fuel economy and equally satisfactory use from the machines.

Numerous attempts have been made to perfect vaporizers for kerosene carburetion. Some of these are fitted with attachments by which the engine may be started with gasoline and kerosene used as quickly as the motor is heated, others are designed to heat the kerosene to whatever temperature is desired to insure carburetion, and there are devices for priming the motor so it may be started. As a matter of fact practically any gasoline carburetor will sufficiently vaporize kerosene once the engine has been started, and the engine can be used without difficulty so long as it is not permitted to become cold. Many of these carburetors and attachments are thoroughly practical and can be used to material advantage, but their values are not understood or realized.

Prof. Benjamin T. Brooks of the bureau of mines of the United States Department of the Interior, is authority for the estimate that the production of gasoline in the United States is approximately 25,000,000 barrels of 42 gallons each, and the statement is that this production is less than the demand for fuel for internal combustion engines. This was not made with a view of influencing prices, uses or conditions, but it is significant than with the constant increase in the number of vehicles, yachts and power plants of all kinds the natural conditions will impel a shortage. Refiners cannot produce gasoline without manufacturing other products. Were gasoline the one product sought there would be of necessity corresponding production of kerosene, oils and paraffin, and these would accumulate in such quantities as would depress prices, for the surplus could not be stored for future consumption. Neither could the tremendous amount of capital that these products would represent remain idle. By this is meant that there is a limit to gasoline production unless the price is sufficiently increased to justify the sacrifice of what are now well established and dependable products.

There is no doubt that gasoline will be the prevailing fuel for pleasure cars, but kerosene is apparently the logical carburetant for freight vehicles. The supposition may be that gasoline is more convenient, and, at the present prices, the economy is hardly worthy of consideration, but today the price of gasoline in bulk will approximate 15 cents, and kerosene is nine cents. Considering the two as having practically the same

value as fuel, the saving by the use of kerosene will be 40 per cent. of the cost of gasoline, or 66 per cent. of the cost of kerosene, on each gallon purchased.

The following shows the savings that would be possible with the use of kerosene as compared with gasoline, with the prices that have been quoted:

Fuel Used Daily, Gals.	Gasoline at at 15c	Kerosene at 9c	Daily Saving	Annual Saving
20	\$3.00	\$1.80	\$1.20	\$360
18	2.70	1.62	1.08	324
16	2.40	1.44	.96	288
14	2.10	1.26	.84	252
12	1.80	1.08	.72	216
10	1.50	.90	.60	180
9	1.35	.81	.54	162
8	1.20	.72	.48	144
7	1.05	.63	.42	126
6	.90	.54	.36	108
5	.75	.45	.30	90
4	.60	.36	.24	72

The above is based on 300 days to the year, and this is not excessive, but whatever the number of working days the ratio will remain the same. The equipment for the use of kerosene may appear to be impractical to those who believe that it is necessary for a truck or wagon to have the same conveniences as a pleasure car. Where the machines are used in traffic a very general custom with drivers is to keep the motor operating at slow speed, which consumes fuel and naturally increases the operating cost.

Kerosene as a fuel is practical. Most all engines now in use will give very good efficiency with no other changes than a carburetor and a priming or starting installation. These are not expensive as a rule, and as indicated above the economy that might be obtained from them is much larger than might be believed without some consideration of the possibilities. There are other qualities of kerosene that are material, these including the minimum loss from handling or volatilization, and the greater security against fire.

The business of the spring department of the Lewis Spring & Axle Company, Jackson, Mich., has been sold to the Alloy Steel Spring Company, which is managed by Fred J. Keiser, who was associated with the Lewis company for a long time. The Lewis company has purchased the E. C. Clark Motor Company, Jackson, and will use the factory for the production of material that will be incorporated in the manufacture of Briscoe cars.

J. L. Elwood has resigned from the service department of the Remy Electric Company, Anderson, Ind., to become general superintendent of the Eureka Manufacturing Company, North East, Penn., and has been succeeded by J. D. Hopper, who was for a considerable length of time associated with the Hamilton Scale Company, Hamilton, O.

The New York City branch of the Gibney Tire & Rubber Company, Conshohocken, Penn., is now under the management of F. F. Phillips, succeeding J. F. Gibney, who has become a travelling representative of the company.

STANDARD TRUCK POLICIES.

Manufacturers' Committee Considers Need of Adoption by Builders and Agents.

The danger from endeavors to standardize motor truck design, and the possibilities of standardization, were considered at length at a meeting of the commercial vehicle committee of the National Automobile Chamber of Commerce at a meeting held May 26 in New York City, which was attended by W. T. White, president of the White Company, chairman; H. Kerr Thomas, assistant manager of the Pierce-Arrow Motor Car Company, and M. J. Budlong, president of the Packard Motor Car Company of New York.

The subject was discussed from various angles and it was agreed that there was a disposition with many engineers to establish standard designs, but wide differences exist in fundamental characteristics between the most successful and widely used makes of motor trucks and wagons, and an insurmountable obstacle to the standardization of such characteristics is the variation in working conditions and the kinds of work that these machines are required to do.

The committee reached the conclusion that the standardization of equipment, on practical lines, would be desirable and entirely practical, this being a detail that would be productive of much greater satisfaction.

The committee also discussed the possibilities for bringing about a clearer recognition of what constitutes reasonable and equitable service with reference to the attention that shall be given to motor trucks in the possession of owners. The opinion reached was that there was great need to have a better understanding and a closer adherence to the terms of the standard warranty, and that because of differences in conditions and practises there was seemingly no possibility of doing more than to define broadly what constitutes service in the general acceptance of the term. The adoption of a definition of service was left open with the understanding that a convention of motor vehicle manufacturers may be called to obtain the views of those who are chiefly concerned and to ascertain a precise basis for agreement.

A branch of the Newlite Manufacturing Company, Newton, Ia., has been established in the New York Life Insurance Company's building at Chicago, Ill., which will be devoted to the sale of the company's motor vehicle lighting systems in Illinois and Indiana. Another branch office will shortly be established at Los Angeles.

Announcement is made by the Royal Equipment Company, Bridgeport, Conn., that Raybestos, its standard asbestos brake lining, for use in light delivery wagons, will be sold with a guarantee of a full year's service, or replacement of the lining with new.

NOVEL KOEHLER "STUNT."

Delivery Wagon Circulates Carrying a Moving Grant Runabout.

A spectacle that has attracted no end of attention in the streets of New York City, and which will undoubtedly be seen in other cities, is that of a Koehler 2000-pound delivery wagon carrying a small runabout that is literally in motion, and the effect is made the more pronounced by a young woman seated in the roadster who has her hands on the steering wheels and is seemingly guiding it. From the viewpoint of the spectator the delivery wagon is converted into a float, this being done by the installation of a platform with skirts that drop a considerable depth the full length of the platform. On the platform is carried a Grant roadster that is finished in white, this making a striking contrast in the surrounding traffic, and in the seat of the runabout a young woman is generally seated.

The machine was first seen leading the annual actors' parade through the principal New York City streets, with Miss Stella Mayhew seated in the runabout, and thereafter it was driven about as a demonstration of the two. The accompanying illustration is a picture made in front of the Natural History Museum. The float was built by the H. J. Koehler S. G. Company, builder of Koehler wagons and eastern distributor of Grant machines. Patents have been applied for and much of the design and construction was completed by V. V. Kranich.

The runabout is mounted with standards beneath the axles which practically support its weight, but the moderately inflated tires rest upon two sets of two rollers which are mounted in the deck of the wagon. The rollers are coupled by gearing, and when exhibited the runabout engine is started and the moving rear wheels drive the rollers, and these in turn move the

forward wheels at the same speed. The high speed ratio is used and the roadster appears to be moving on the deck of the wagon. In addition the power taken from the rollers turns signs that are mounted in the skirts of the platform, these moving so long as the wheels of the runabout are in motion. Of course the wagon is operated independently of the pleasure car.

There is some probability that the exhibit will be sent across the continent, which event may be productive of desirable attention wherever it shall be seen.

AUTO SCHOOL CHARTERED.

The Stewart Automobile Academy of New York City has been established as a recognized educational institution of New York State, it having received recognition by the state board of regents, which determines the standing of all schools and colleges and fixes the standards of education. The academy for a long time sought to have its diploma recognized and after a considerable period of observation the board gave its approval. The school has been in existence for a number of years and has graduated several thousand students. It is said to be the first institution of the kind in the United States to be thus recognized.

NEW YORK TRUCK REGISTRATION.

During the three months ending May 1, 13,807 delivery wagons and trucks and machines rated as commercial vehicles were registered in New York State, which is indicative of a very large gain, for the total number registered during 1913 was 13,780. Of this number 8833 were registered in New York City, and 3524 were new machines, which, if taken as a basis, would indicate that practically 40 per cent. of the total registration was placed in service for the first time. The total registration in 1912 was 9806, and there was a gain of 3974 during 1913, or slightly in excess of 40 per cent. Thus during three months of 1914 the gain has been equal in percentage to that of 1913, and with the probable increase during the remainder of the year there is every reason to believe that the percentage will be close to, if not quite, 75 per cent. The motor trucks and wagons registered are about 12 per cent. of the total registration of automobile vehicles. With this as a basis there is probability that the total truck registration for the year will be very close to 19,000, and possibly 20,000.

Koehler Ton Delivery Wagon, Carrying a Grant Roadster and Miss Stella Mayhew, Which Headed the Annual Actors' Parade in New York City.

ELECTRIC VEHICLE PRACTISE.

Systematic Undercharging and Overcharging of Batteries to Minimize Gassing and the Deterioration of the Electrodes---Practical Treatment That Develops Capacity, Insures Long Life and Minimizes Current Consumption and Repair Cost.

By William W. Scott.

BATTERY charging can best be done by putting enough current into the cells and doing this with a minimum of gassing. Obviously, whatever current is used in excess of the required amperage is productive of gas that is liberated, which is a source of expense, and in addition to this there is the unnecessary wear upon the electrodes, so that there are two very logical and satisfactory reasons for care.

The positive plates of a cell may be damaged by overcharging if there be any abnormal gassing, but they will endure charging at low rates with very little deterioration. The negative plates may not be fully charged with the cell voltage reading 2.5, so one may understand that voltage does not always indicate plate condition. As a matter of fact long continued charging will directly benefit the negative electrodes, so long as there is lead sulphate to be reduced. If the sulphate is not eliminated the negative plates will not have full capacity and the battery will not have its rated efficiency, this resulting in a loss of work.

The requirements of the two electrodes are almost diametrically opposite, and by careful observation engineers have learned that the cells can be best protected by so charging that there will be little if any gassing, for it is entirely practical to minimize the effect upon the positive plates and by continuance of the method to thoroughly reduce the sulphate of the negative plates. For the reason that gassing will inevitably result when a certain condition has been reached, the necessity of reducing the amperage when there is a free liberation of gas is apparent.

The possibilities of systematic and careful charging are limited, but very high engineering authorities maintain that there can be an increase of at least 20 per cent. in battery life, and in some instances considerably in excess of this merely by exercising care and reasonable judgment. When one considers the possibilities for battery capacity falling below normal rating the very large saving that is practical is evident. It is not too broad a statement to say that by following a formula in the charging of cells one can insure from 15 to 25 per cent. useful work more than is claimed by the manufacturers. As this is absolutely clear gain there is the best of reason why the owner of a vehicle should obtain this service, and at the same time still further benefit by the minimum current consumption.

The battery man directing the charging should un-

derstand that voltage is not a constant by which to judge. There will be variation from several reasons, the age of the electrodes, the specific gravity of the electrolyte and the temperature, and observation is the greatest factor in attention. Gassing will follow when a condition has been reached, and when the amperage has been reduced the voltage will continue until a maximum has been reached and gassing is again evident. Or it is practical to reduce the amperage sev-

eral times and continue the charging over a long period of time.

It may be well to emphasize here what has been stated relative to "boosting", when high amperage can be used, that so long as the cell will absorb the energy without gassing there will be no untoward result—only when the gas is liberated freely will deterioration begin, but at this point "boosting" must posi-

Form of Record for Gravity Charging Used by the Rochester Railway & Light Company, the Entries Covering Use, Mileage and Observations During the Charge, Each Sheet Providing for a Month.

tively cease, which does not mean that a charge is complete. Charging, however, is intended to completely restore the amperage capacity of the battery, and this is an entirely different proposition, for the energy must be supplied and the gassing prevented.

The experience has been that with the battery cell designed for the eight-hour rate, current supplied for approximately five hours at the starting rate, and continued from two to three hours at the finish rate, will meet the average requirement in a fairly practical way, but this is by no means certain or accurate. While it is true that a charge of from seven to eight hours will yield fairly good results, this does not mean that this will be ideally productive or protective.

The actual determining factor is maximum voltage, or, better still, gassing and specific gravity with voltage as a check. Final voltage will vary with the age of the electrodes, the new plates showing the highest, and there will be the temperature, which will have about the same influence on either old or new plates. Time is necessary in charging because of the necessity of reducing the sulphate, and this is especially true of the negative plates, where the capacity is absolutely dependent upon the condition. Forcing the charge beyond the stage where gassing is manifested affects the positive plates, which means that to restore the negative plates the positive plates are deteriorated.

The battery manufacturers have not agreed upon conditions of treatment of the cells. In some instances an overcharge is advocated once a week, in others once in two weeks, and occasionally once a month, but all are united in the benefit of the overcharge as a means of making certain that the sulphation of the plates is reduced. Batteries possess the same general characteristics, and one might assume that practise could consistently be the same with all, but while in a broad way this will hold true, it is also a fact that details differ essentially with each.

For instance, with the Gould cells the manufacturer specifies that the voltage readings should be taken every half hour during the period the battery is charging, and the charge should be maintained for a half hour after the voltage has remained stationary,

or reached its maximum. These readings must be taken while the battery is charging and at the rate specified. Equalizing of the electrolyte is advocated once a week, no matter what the service the vehicle is in, that the specific gravity be maintained as near 1.275 specific gravity as is possible. Recommendation is also made that the battery be given an overcharge once a week if used for freight service, and once in two weeks if used for pleasure, this overcharge to be continuance of the low final rate for from three to four hours after the battery has been charged in the normal manner. Equal stress is placed upon making a test discharge once every two weeks after the usual work for the day has been done by discharging at the rate of discharge specified in the catalogued rating until an average of 1.7 volts a cell has been reached. Such discharges necessitate voltage readings at intervals during the period of discharge, the record of necessity being that from the beginning of the observation until the average of 1.7 volts a cell has been indicated. Such tests may not cover a wide range, particularly if the vehicle is doing work well up to its mileage capacity, but the determinations are expected to be conclusive, for by the readings of a low-reading voltmeter and specific gravity the condition of any cell can be established.

The user of the Exide batteries is impressed by the maker with the fact that no additional mileage will result from excessive overcharging, and emphasis is made that any decidedly noticeable increase in temperature is a direct indication of such excess. Stress is placed upon the variation of voltage and recommendation is made that the guide be the maximum rather than a standard, while test of the specific gravity of several cells should be made near the end of the charge. By comparison of these with the voltage a very accurate check can be obtained. Though the specific gravity tests may not be taken each charge, the statement is made that each cell should be tested at least once every two weeks. Attention is directed to the fact that the input of current will be governed very largely by the output, but from 10 to 15 per cent. more will be required for charging than was discharged. Once in two weeks the charge should

be prolonged and continued for one hour after the gravity of the electrolyte has stopped rising. When such charges are given the battery cells should each be tested for specific gravity, uniformity being the principal purpose to obtain from such test.
